Operations and Intelligence Report
METROBANK

April 2016

BEST IN CLASS – INFORMATION SECURITY
INTELLIGENCE AND OPERATIONS

Table of Contents

1. About This Report

The purpose of this document is to report on the "state" of security for your organization. It must be noted that GLESEC bases its information analysis on the systems under contract. The information generated by these systems is then aggregated, correlated and analyzed. The more complete the set of systems under contract the more accurate and complete the results will be. The report is organized to provide an executive summary with recommendations (as necessary or applicable) followed by more detailed information.

We at GLESEC believe information security is a holistic and dynamic process. This process requires on-going research and follow up. Holistic since no single "device" can provide the security necessary for an organization. Technology alone cannot provide the security necessary, but people that understand the operations and information generated by the security devices are a key to proper security. The process is dynamic since due to the nature of Internet security given the constant discovery of new security vulnerabilities and exploits, the proliferation of hacking tools that make it easier for script-kiddies with minimal knowledge to cause damage. The increase in malware, phishing, insider threats, espionage, organized crime, intellectual property theft, and hacktivism are the very cause of information security exposure and are most commonly driven by financial gain.

2. Confidentiality

GLESEC considers the confidentiality of client's information as a trade-secret. The information in this context is classified as:

a) Client name and contact information
b) System architecture, configuration, access methods and access control
c) Security content

All the above information is kept secure to the extent in which GLESEC secures its own confidential information.

3. Scope of This Report

GLESEC Contracted Services

MSS: Managed Security Service (full outsourcing)

Service	Manufacturer	Model	Update Expiration	Service Expiration
MSS-APS	Radware	DefensePro 516 ODS2-S1	06/1/2016	06/1/2016
MSS-APS	Radware	AppWall ODS1XL	06/1/2016	06/1/2016
MSS-VME	Beyond Security	AVDS	06/1/2016	06/1/2016

4. Executive Summary

This report corresponds to the period from April 1, 2016 to April 30, 2016.

This month we are seeing an increase in attack activity from prior month of about 32% and an increase in critical attacks from prior month of about 16%. Most of the attacks are less than a minute and up to five minutes and they target multiple ports. Most of the attacks seem to be of reconnaissance (scanning). About 69% of the attacks for this month came from scanning which can be considered reconnaissance and is what precedes further attacks. The attacks are, as usual others mostly from the US, Russia and Panama, as the three top sources. A significant number of attacks are scanning which can be considered reconnaissance and is what precedes further attacks.

Five out of twenty-three of the hosts that are seen from the Internet have vulnerabilities ranging from Medium to Low with a total of 39 vulnerabilities encountered this month. This is a significant increase in vulnerabilities (17 prior month).

The GLESEC operated systems have been stable with **99.978%** availability and good response time.

Risk Value

To provide a way to quantify the risk of a Company, Glesec introduces a definition for a metric value to capture the exposure risk that allow to evaluate the objective vulnerabilities and also the record of change over time. This procedure to qualify can be used to evaluate the ROI in the security measures we have implemented.

It is important to mention that this metric considers a median value for the vulnerabilities classified as ¨high¨, ¨medium¨ and ¨low¨, given them a value of 100% 50% and 10% to each, so the factor of the total number of system that are vulnerable.

This takes into consideration all of the vulnerabilities, but is important to point out that this values (100, 50 and 10) are arbitrary chosen by us, so this measure can in time change as we understand more of the risk involved. We can use this metric to evaluate the progress in time and to compare one over the other using a common amount set.

Total IP's Scanned			IP's Vulnerable
23			5
Risk Distribution			
High	Medium	Low	Total
0	12	27	39
Risk Value		0.048	
Vulnerabilities Weighted Sum			0.223

According to the metrics:

RV= 0.048

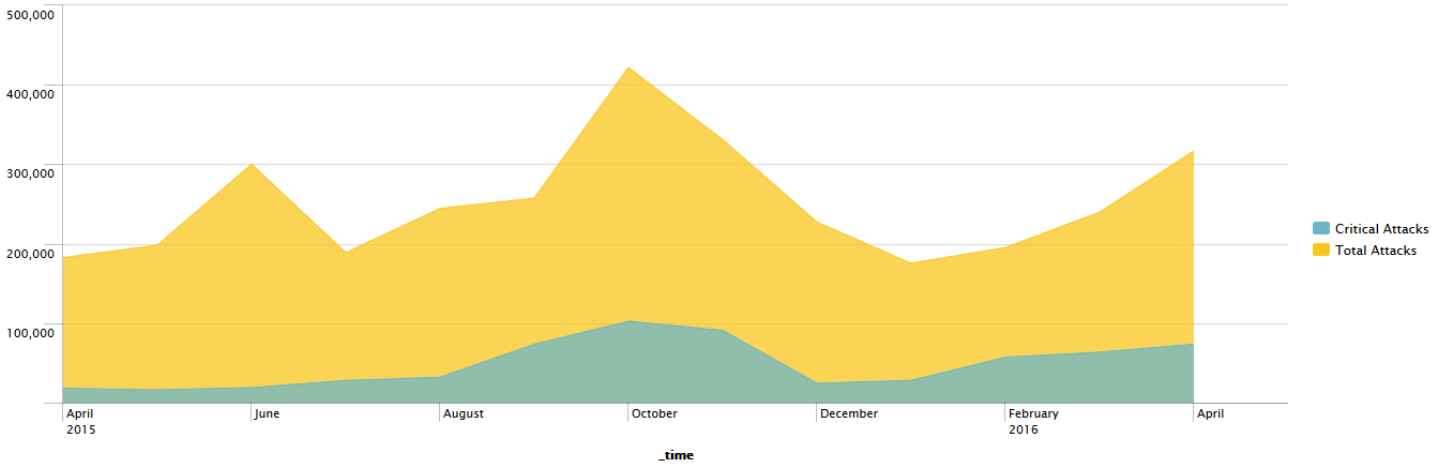
The following values are to clarify RV:
RV=1 Points to every IP address in the infrastructure that are susceptible to attacks
RV=0 Points to no IP address in the infrastructure are susceptible to attacks
RV=0.1 Point to 1/10 IP address in the infrastructure that are susceptible to attacks

Attack Summary

Based on the information gathered from the DefensePro during this period **316,764** attacks on METROBANK, **73,594** of which were considered critical were all stopped by the Radware devices.

METROBANK receives an average of **252,153** total attacks and **8,278** critical attacks on a monthly basis which equates to an average of **48,240** total daily attacks and **1,584** critical daily attacks. As the graph illustrates total attack levels in relation to the previous report period totaled **239,627** total attacks and critical attacks in compared with a last period's total of **63,540**.

This statistical graph provides the count of critical and total attacks blocked per month calculated on a rolling 12 month period (Last 12 months)

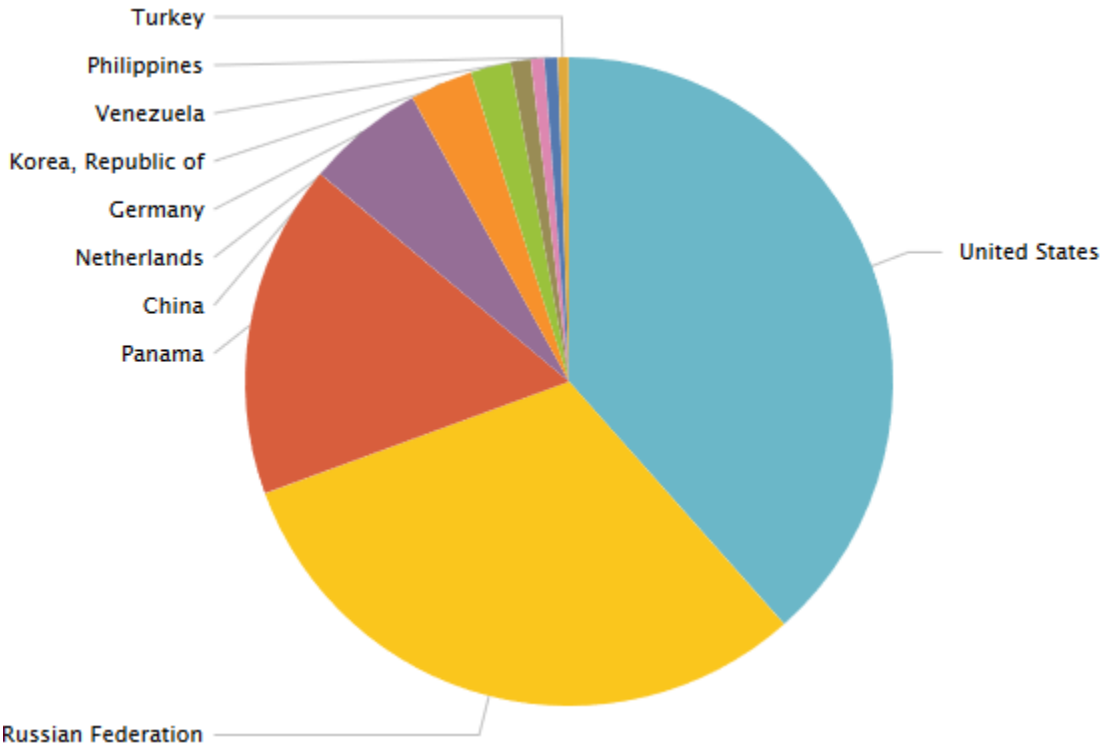


Comparison of previous month with month actual.

Description	March	April
Total Attack	239,627	316,764
Critical Attacks	63,540	73,594
Monthly attack average	248,997	252,153
Daily Attack Average	8,154	8,278
Monthly Critical attack average	43,744	48,240
Daily Critical Attack Average	1,432	1,584

Geography

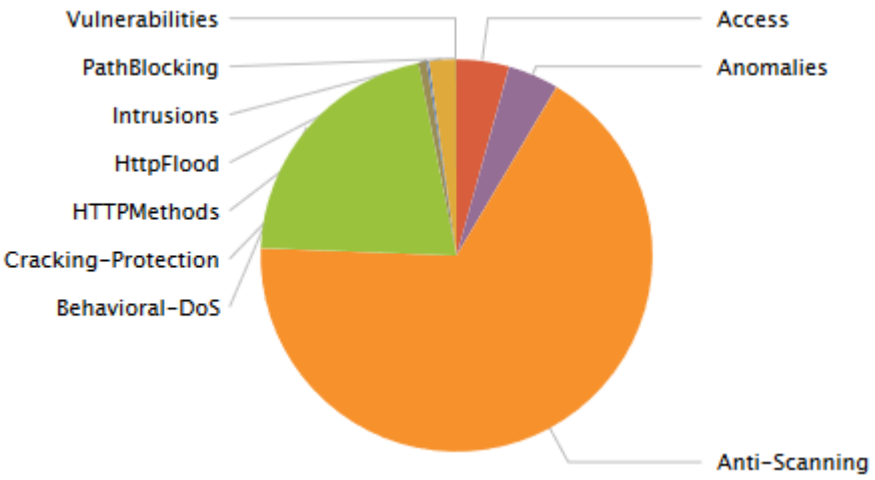
The vast majority of attacks on Metrobank originated geographically from the following Top 10 countries: **United States, Russian Federation, Panama, China, Netherlands, Germany, Republic of Korea, Venezuela, Philippines and Turkey** listed in order of frequency. The attacks that we observed are happening to companies all around the world. Geographic borders offer little or no protection against cyber-attacks, in fact just the opposite is true offering more opportunity for anyone to carry out an attack.



*Please view the Maps, and **Graph: Top 10 Attacking Countries Blocked**, **Graph: Top 10 Attacking Countries Blocked by Attack Type**, **Graph: Top 10 Attacking Countries Blocked by Protocol** available in the Security Intelligence section of the report.

Category Distribution

Category distribution for this report period is illustrated and detailed below.



Scanning accounted for 67.1 % of attacks during this report period

Network-wide Anti-Scanning protections dropped enumeration attempts which otherwise thwart any effort for threat modelling, commonplace after the information gathering phase of a targeted or planned attack.

Packet Anomalies accounted for 4.2 % of attacks during this report period

This anomalous traffic is usually caused by attacks or evasion tactics directed at the network devices such as firewalls in order to bypass their functions which if allowed to pass could permit scanning of the internal network or overloading the central processing unit of the device rendering it unusable and effectively causing a network bottleneck or DoS condition. They are also used as a method to collapse the underlying network infrastructure with packet crafting tools used by threat agents to interrupt services or distract security teams with volumetric attacks while more targeted attacks are directed at important assets to allow for data exfiltration. Packet Anomalies can also be caused by applications that do not adhere to RFC standards.

Access accounted for 4.3 % of attacks during this report period

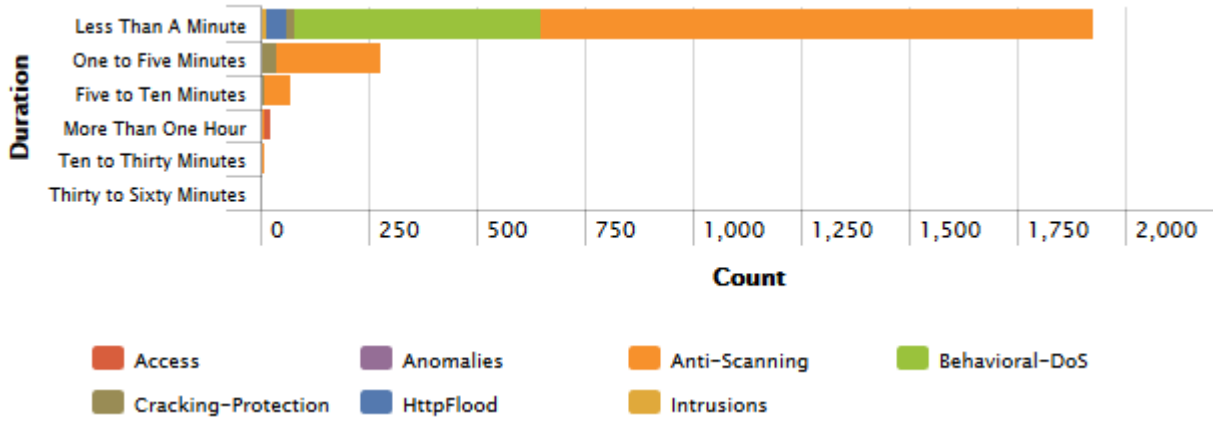
Access category relates directly to blacklists configured by GLESEC on the DefensePro for known threat sources.

Intrusions accounted for 2.2 % of attacks during this report period

These include vulnerability-based threats such as: Worms and Botnets; Trojan horses and the creation of backdoors; Vendor-specific exploitation vulnerabilities in products e.g., Microsoft, Oracle; Exploitation of vulnerabilities in applications such as web, mail, VoIP, DNS, SQL; Spyware, Phishing, anonymizes.

Duration

Attack duration for specific categories for this report period is illustrated below.



Bandwidth

Behavioral-DoS dropped **40.04 Gbps**, Anti-scanning protection dropped **1.34 Gbps**, Access dropped **0.47 Gbps** of total traffic, **0.23 Gbps** dropped by Intrusion protection rules, Cracking protection dropped **0.01 Gbps** and Packet Anomalies dropped **0.02 Gbps**. A total of **42.11 Gbps** of malicious traffic was discarded this period.

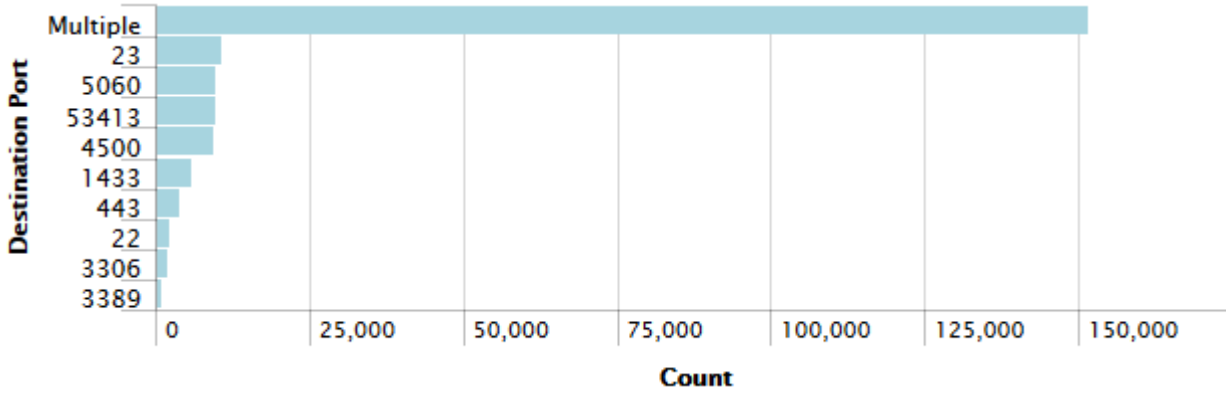
Category	Gbps	Mbps
Behavioral-DoS	40.04	41001.00
Anti-Scanning	1.34	1374.88
Access	0.47	484.17
Intrusions	0.23	234.65
Anomalies	0.02	19.45
Cracking-Protection	0.01	13.18
Total Bandwidth in Gbps/Mbps	42.11	43127.33

*Please view the **Bandwidth Information**, and **Graph: Bandwidth by Blocked Threat Category by Hour of Day** and **Graph: Top Attacks Blocked by Bandwidth** and **Graph: Attack Categories Blocked by Bandwidth** available in the Security Intelligence section of the report.

Port Activity

The advanced intrusion detection and prevention capabilities offered by the DefensePro IPS NBA, DoS and Reputation Service provides maximum protection for network elements, hosts and applications. It is composed of different application-level protection features to prevent intrusion attempts such as worms, Trojan horses and single-bullet attacks, facilitating complete and high-speed cleansing of all malicious intrusions.

The DefensePro assisted in preventing attacks directed at network and server level which were directed at well-known port numbers: **80** (http), **1433** (ms-sql), **8080** (http-alt), **4500** (ipsec-nat-t), **443** (https), **5060** (sip), **23** (telnet), **22** (ssh), **3306** (mysql) in order of frequency for this report period.

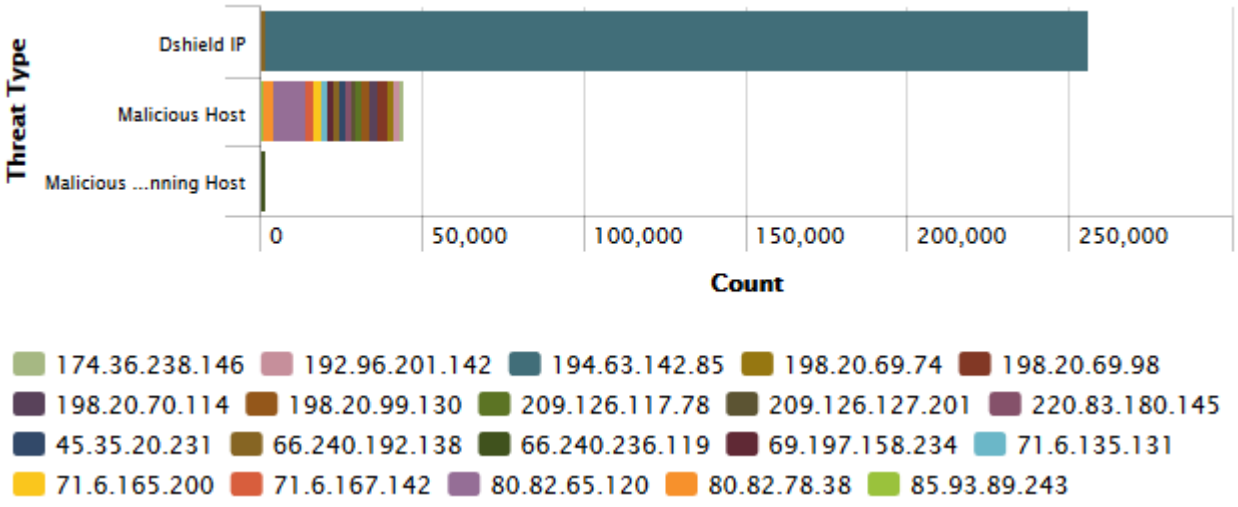


Port number information utilized is based on IANA Service Name and Transport Protocol Port Number Registry and additional outside sources are used to illustrate the relationship to commonly exploited attacks vectors.

*Please view the **Port Information**, and **Graph: Attacks Blocked by Destination Port** and **Graph: Top Probed Applications Blocked** available in the Security Intelligence section of the report.

Known Threat Sources by Threat Type

260,000 attacks on METROBANK are from known threat sources that have been compiled and correlated with attack source IPs gathered from the DefensePro attack logs and outside sources such honeypots, known malicious sources, vulnerability databases, relationships with CERT and CSIRT teams that GLESEC possesses, together with various other threat feeds.



Vulnerability Summary

The following network ranges for METROBANK was scanned for vulnerabilities.
A total of **23** hosts were scanned **5** of which were found to be vulnerable.
Vulnerabilities were detected for the following host IPs:

Vulnerable Hosts	High	Medium	Low	Total
190.34.183.158			4	4
190.34.183.144			4	4
190.34.183.139			4	4
190.34.183.132			1	1
190.34.183.131			4	4

Vulnerability –Current Month and Previous Month

A comparison of persistent vulnerabilities of the current month and previous month.

ip	Previous_Month	Current_Month
190.34.183.131	4	4
190.34.183.132	1	1
190.34.183.139	4	4
190.34.183.144	4	4
190.34.183.158	4	4

Please view **Recommendations** for more details.

Risk Distribution

Category distribution for this report period is illustrated and detailed below.

Based on the information gathered from the GLESEC Automated Vulnerability Detection System (AVDS) a total of **17 Vulnerabilities** were found which consisted of **0 High Risk Vulnerabilities, 0 Medium Risk Vulnerabilities** and **17 Low Risk Vulnerabilities** during this period.

Scan Name	High	Medium	Low	Total
Metrobank			17	17

High risk vulnerabilities accounted for 0 % of the discoveries during this report period

High are defined as being in one or more of the following categories: Backdoors, full Read/Write access to files, remote Command Execution, Potential Trojan Horses, or critical Information Disclosure (e.g. passwords).

Medium risk vulnerabilities accounted for 0 % of the discoveries during this report period

Medium describes vulnerabilities that either expose sensitive data, directory browsing and traversal, disclosure of security controls, facilitate unauthorized use of services or denial of service to an attacker.

Low risk vulnerabilities accounted for 100 % of the discoveries during this report period

Low describes vulnerabilities that allow preliminary or sensitive information gathering for an attacker or pose risks that are not entirely security related but maybe used in social-engineering or similar attacks.

Vulnerability Categories

Most frequent type of vulnerabilities.

1	Preliminary Analysis	9	Firewalls	17	Network Devices
2	SMB/NetBIOS	10	SSH Servers	18	Malformed Packets
3	Simple Network Services	11	Mail Servers	19	Proxy Servers
4	Policy Checks	12	SQL Servers	20	Wireless AP
5	Web Servers	13	FTP Servers	21	Webmail Servers
6	RPC Services	14	Server Side Scripts	22	NFS Services
7	Backdoors	15	SNMP Services	23	Printers
8	Encryption and Authentication	16	DNS Servers		

The list below indicate your vulnerability most frequent:

SMB/NetBIOS with **8** detections total vulnerabilities, Preliminary Analysis in the category **4** detected, Simple Network Services **4**, and Encryption and Authentication with 1 detections for the report period.

Category	High	Medium	Low	Total
SMB/NetBIOS			8	8
Preliminary Analysis			4	4
Simple Network services			4	4
Encryption and Authentication			1	1

SMB/NetBIOS vulnerabilities accounted for 47.1 % of the discoveries during this report period

SMB/NetBIOS vulnerabilities could allow remote code execution on affected systems. An attacker who successfully exploit these vulnerabilities could install programs; view, change, or delete data; or create new accounts with full user rights. Firewall best practices and standard default firewall configurations can help protect networks from attacks that originate outside the enterprise perimeter. Best practices recommend that systems that are connected to the Internet have a minimal number of ports exposed.

Simple Network Service vulnerabilities accounted for 23.5 % of the discoveries during this report period

Simple Network vulnerabilities affect protocols like NTP, ICMP and common network applications like SharePoint among others. This is not meant to be a comprehensive list.

Preliminary Analysis vulnerabilities accounted for 23.5 % of the discoveries during this report period

Authentication and encryption are two intertwined technologies that help to insure that your data remains secure. Authentication is the process of insuring that both ends of the connection are in fact who they say they are. This applies not only to the entity trying to access a service (such as an end user) but to the entity providing the service, as well (such as a file server or Web site). Encryption helps to insure that the information within a session is not compromised. This includes not only reading the information within a data stream, but altering it, as well.

While authentication and encryption each has its own responsibilities in securing a communication session, maximum protection can only be achieved when the two are combined. For this reason, many security protocols contain both authentication and encryption specifications.

Encryption and Authentication vulnerabilities accounted for 5.9 % of the discoveries during this report period

Authentication and encryption are two intertwined technologies that help to insure that your data remains secure. Authentication is the process of insuring that both ends of the connection are in fact who they say they are. This applies not only to the entity trying to access a service (such as an end user) but to the entity providing the service, as well (such as a file server or Web site). Encryption helps to insure that the information within a session is not compromised. This includes not only reading the information within a data stream, but altering it, as well.

While authentication and encryption each has its own responsibilities in securing a communication session, maximum protection can only be achieved when the two are combined. For this reason, many security protocols contain both authentication and encryption specifications.

5. Recommendations

GLESEC recommends for METROBANK to address the following vulnerabilities assigned a Low Risk by the GLESEC AVDS.

Systems Affected

190.34.183.131, 190.34.183.139, 190.34.183.144, 190.34.183.158

Description

ICMP Timestamp Request / Preliminary Analysis

The remote host answers to an ICMP timestamp request. This allows an attacker to know the time and date on your host.

Impact

This may help attackers to defeat time based authentications schemes.

Solution

See solution provided at: http://www.beyondsecurity.com/faq/questions/54/how-can-i-mitigate-icmp-timestamp

Systems Affected

190.34.183.132

Description

IPSEC IKE Detection / Encryption and Authentication

The remote host seems to be enabled to do Internet Key Exchange (IKE). This is typically indicative of a VPN server. VPN servers are used to connect remote hosts into internal resources.

Solution

You should ensure that:

1) The VPN is authorized for your Companies computing environment
2) The VPN utilizes strong encryption
3) The VPN utilizes strong authentication

Systems Affected

190.34.183.158

Description

NTP Variables Reading / Simple Network services

It is possible to determine a lot of information about the remote host by querying the NTP variables - these include OS descriptor, and time settings. Theoretically one could work out the NTP peer relationships and track back network settings from this.

Impact

Attackers can gain critical information about the host.

Solution

Set NTP to restrict default access to ignore all info packets: restrict default ignore

Systems Affected

190.34.183.131, 190.34.183.139, 190.34.183.144, 190.34.183.158

Description

NetBIOS Information Retrieval/SMB/NetBIOS

We tried to use NetBIOS over TCP/IP to find information about your computer. The following information was retrieved:

190.34.183.131:
The following 3 NetBIOS names have been gathered
MTBWEBSITEGOV = File Server Service
METROBANK = Workgroup / Domain name
MTBWEBSITEGOV = Computer name

The remote host has the following MAC address on its adapter:
00:50:56:aa:16:23

190.34.183.139:
The following 6 NetBIOS names have been gathered
APPSERVER = Computer name
METROBANK = Workgroup / Domain name
APPSERVER = File Server Service

METROBANK = Browser Service Elections
METROBANK = Master Browser
__MSBROWSE__ = Master Browser

The remote host has the following MAC address on its adapter:
00:50:56:84:29:2f

190.34.183.144:
The following 3 NetBIOS names have been gathered
TEC-APC = Computer name
METROBANK = Workgroup / Domain name
TEC-APC = File Server Service

The remote host has the following MAC address on its adapter:
00:0c:29:ef:f6:08

190.34.183.158:
The following 4 NetBIOS names have been gathered
MTBOFICONTAB = Computer name
METROBANK = Workgroup / Domain name
MTBOFICONTAB = File Server Service
METROBANK = Browser Service Elections

The remote host has the following MAC address on its adapter:
00:1e:4f:e5:e1:7e

Impact

If NetBIOS is enabled and open to the outside, attackers may try to reach shared directories and files. This also gives sensitive information to the attacker such as the computer name, domain, or workgroup.

Solution

The recommended solution is to block it in your firewall (or even your router, using ACLs). If you have 2 network interfaces, remove the binding for 'disk and printer' sharing from the external network interface.

For your general information, here is how to disable NetBIOS:
http://www.securiteam.com/windowsntfocus/3E5PUR5QAY.html

Systems Affected

190.34.183.131, 190.34.183.139, 190.34.183.144, 190.34.183.158

Description

Windows Host NetBIOS to Information Retrieval/SMB/NetBIOS

The remote host listens on udp port 137 and replies to NetBIOS nbtscan requests. By sending a wildcard request it is possible to obtain the name of the remote system and the name of its domain.

190.34.183.131 : netbios-ns (137/udp):

The following 3 NetBIOS names have been gathered
MTBWEBSITEGOV = File Server Service
MTBWEBSITEGOV = Computer name
METROBANK = Workgroup / Domain name

The remote host has the following MAC address on its adapter:
00:50:56:aa:16:23

190.34.183.139 : netbios-ns (137/udp):

The following 6 NetBIOS names have been gathered
APPSERVER = Computer name
METROBANK = Workgroup / Domain name
APPSERVER = File Server Service
METROBANK = Browser Service Elections
METROBANK = Master Browser
__MSBROWSE__ = Master Browser

The remote host has the following MAC address on its adapter:
00:50:56:84:29:2f

190.34.183.144 : netbios-ns (137/udp):

The following 3 NetBIOS names have been gathered
TEC-APC = Computer name
METROBANK = Workgroup / Domain name

TEC-APC = File Server Service

The remote host has the following MAC address on its adapter:
00:0c:29:ef:f6:08

190.34.183.158 : netbios-ns (137/udp):

The following 4 NetBIOS names have been gathered
MTBOFICONTAB = Computer name
METROBANK = Workgroup / Domain name
MTBOFICONTAB = File Server Service
METROBANK = Browser Service Elections

The remote host has the following MAC address on its adapter:
00:1e:4f:e5:e1:7e

Systems Affected

190.34.183.131, 190.34.183.139, 190.34.183.144

Description

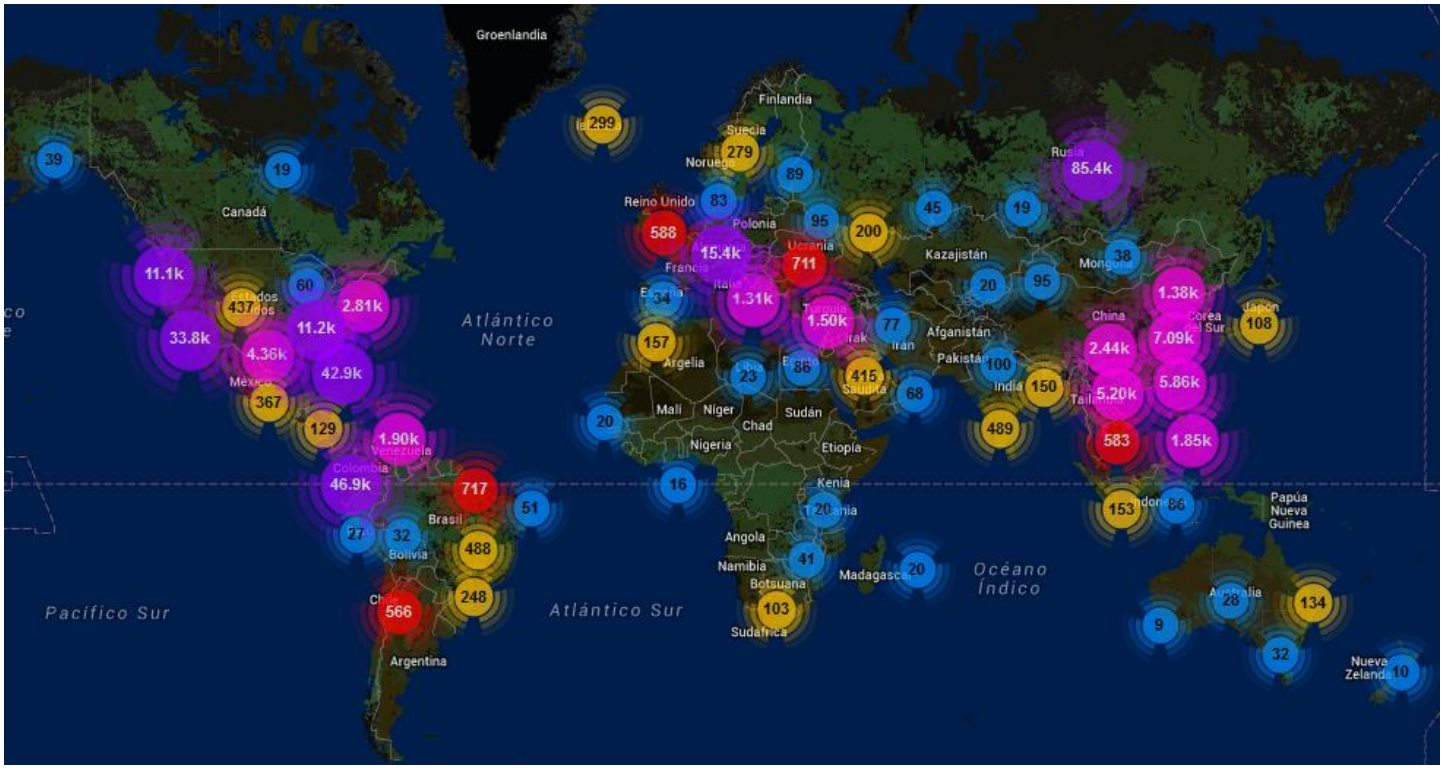
VMWare Host Detection/Simple Network services

The remote host seems to be a VMWare virtual machine running the Microsoft Windows Operating system. Since it is physically accessible through the network, you should ensure that its configuration matches the one of your corporate security policy.

6. Security Intelligence

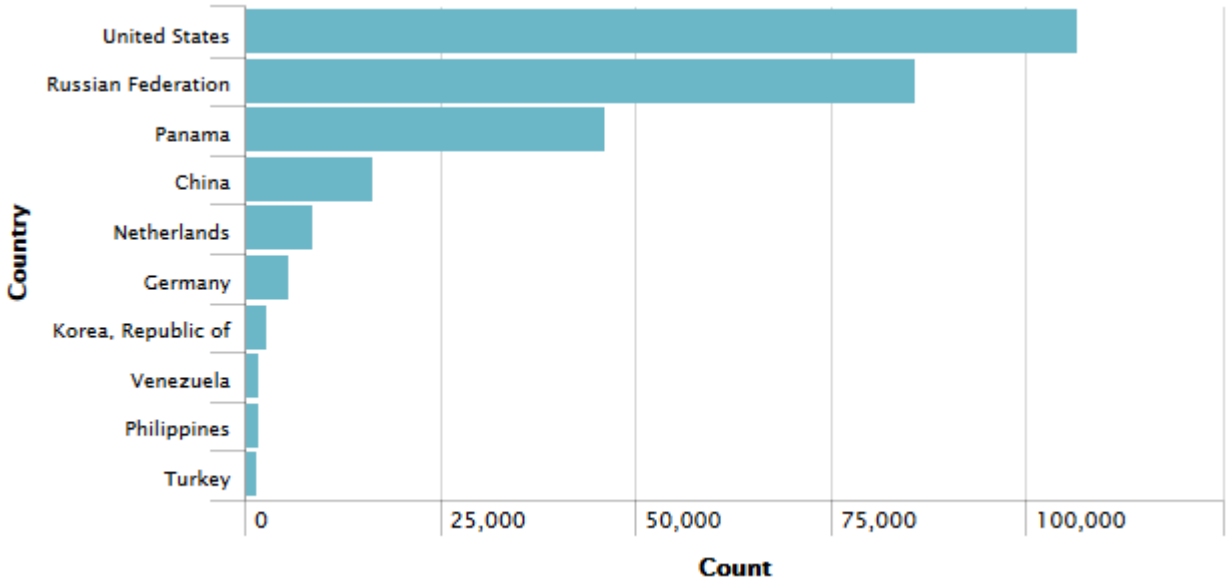
The purpose of this section is to highlight intelligence gathered from the devices under contract as well as outside sources such honeypots, known malicious sources, vulnerability databases, relationships with CERT and CSIRT teams that GLESEC possesses, together with various other threat feeds.

The vast majority of attacks on METROBANK originated geographically from the following Top 10 countries: **United States, Russian Federation, Panama, China, Netherlands, Germany, Republic of Korea, Venezuela, Philippines and Turkey** listed in order of frequency. The attacks that we observed are happening to companies all around the world. Some results do not include location information that allows map plotting.



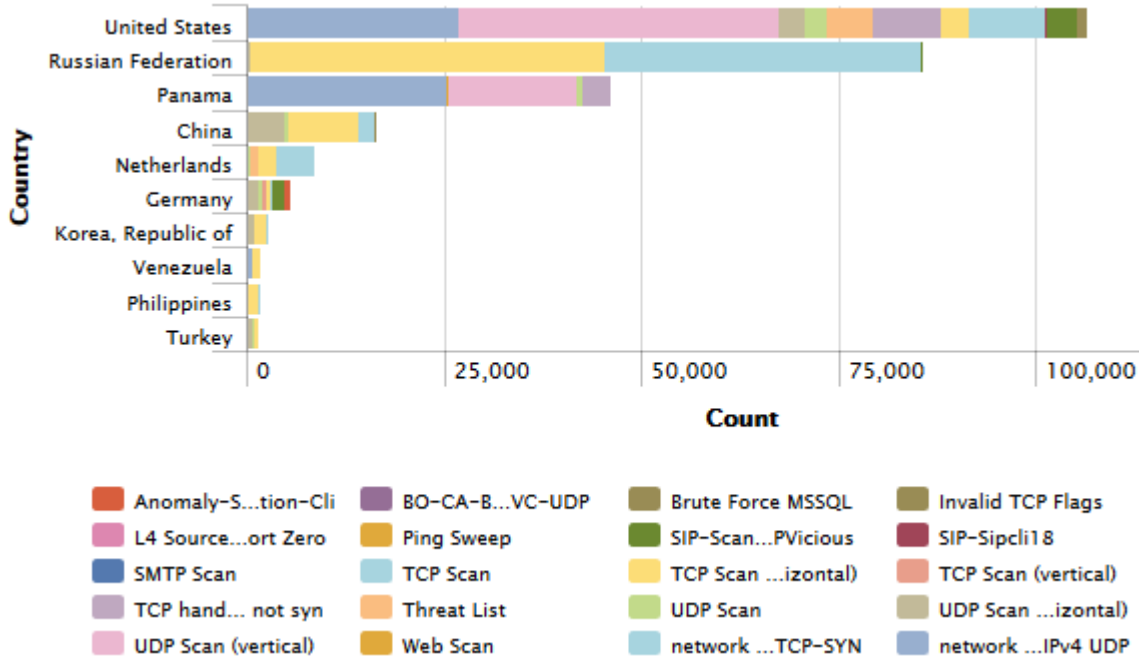
Graph: Top 10 Attacking Countries Blocked

This report provides the count of total attacks blocked by country



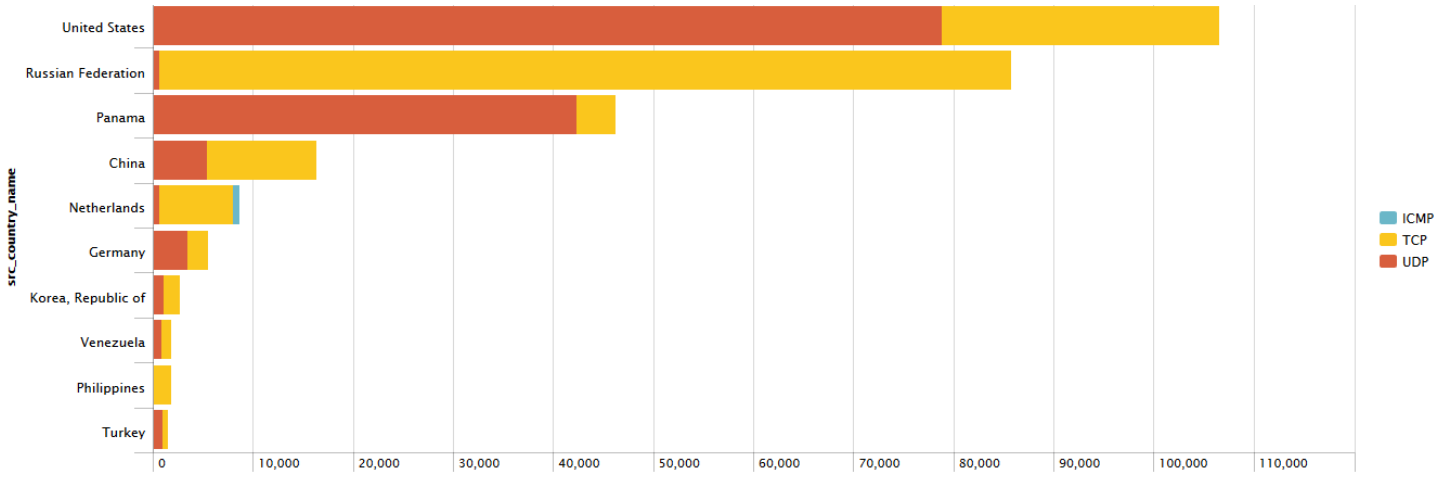
Graph: Top 10 Attacking Countries Blocked by Attack Type

This report provides the count of total attacks types blocked by country



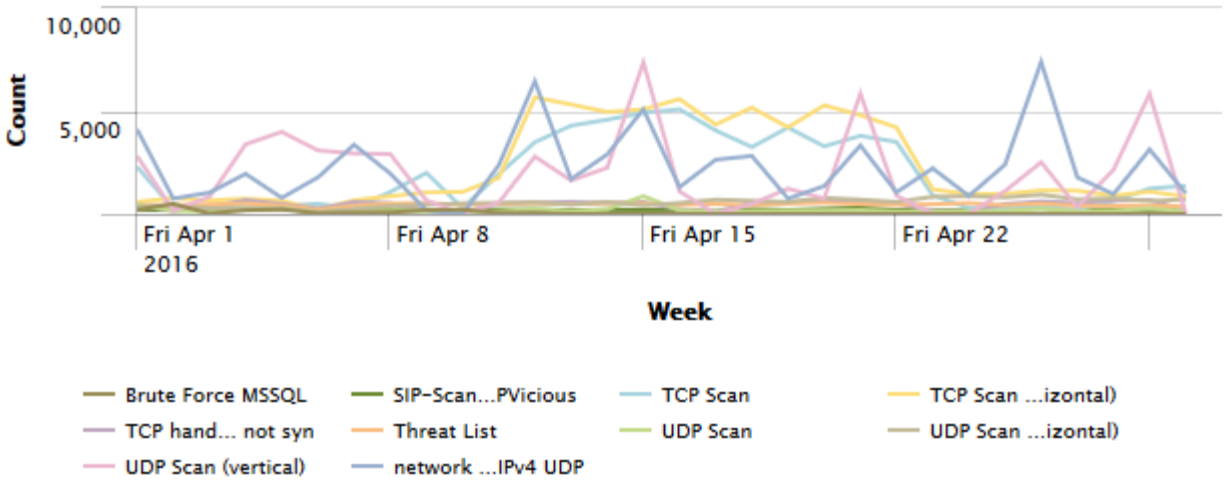
Graph: Top 10 Attacking Countries Blocked by Protocol

This report provides the count of attack protocols blocked by country



Graph: Attacks Types Blocked by Week

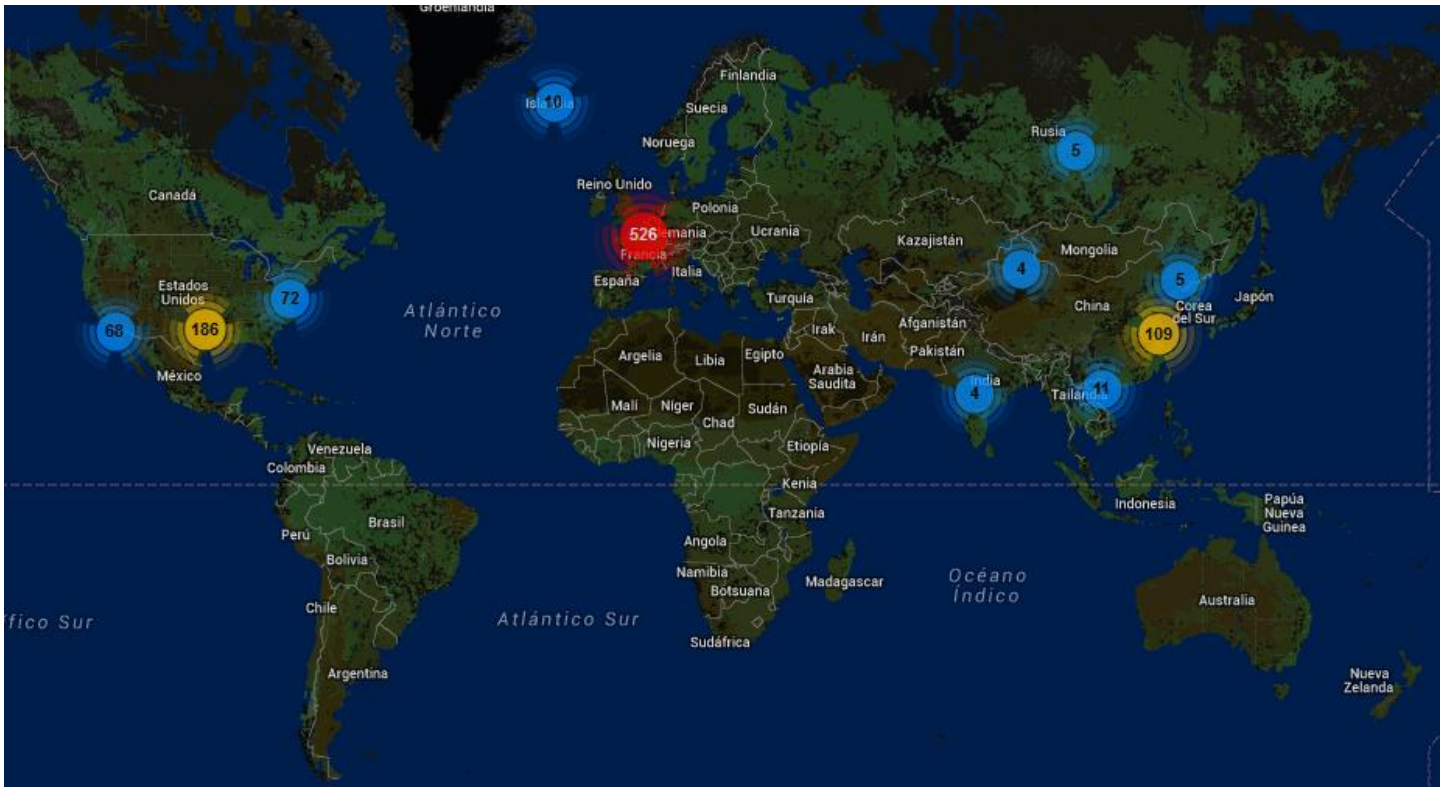
This report provides the count of attacks blocked by week



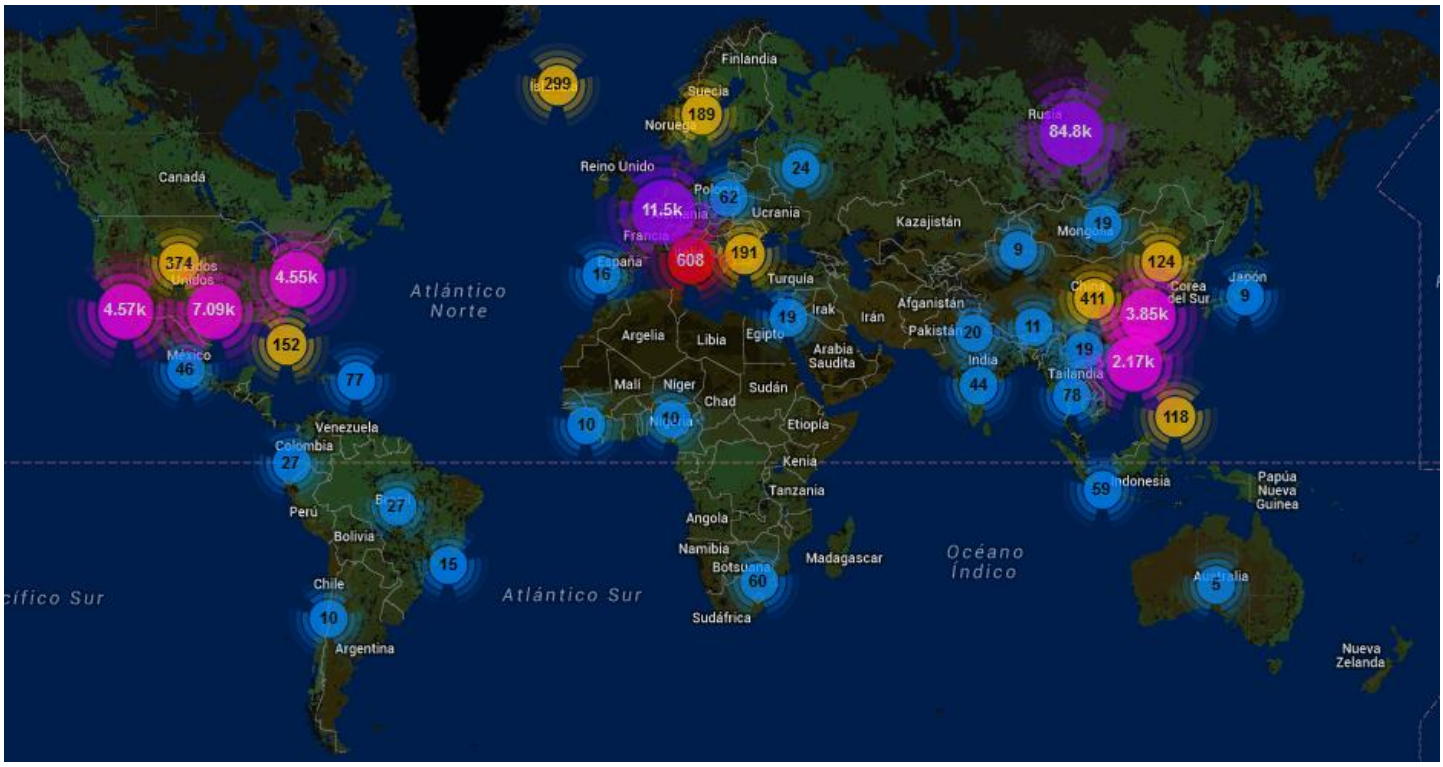
Known Threat Source Information

367,982 attacks on METROBANK are from known threat sources that have been compiled and correlated with attack source IPs gathered from the DefensePro attack logs and outside sources such honeypots, known malicious sources, vulnerability databases, relationships with CERT and CSIRT teams that GLESEC possesses, together with various other threat feeds.

121,577 attacks on METROBANK from the DNS Blacklist obtained by correlating values from the Project Honey Pot Database. Some results do not include location information that allows map plotting.

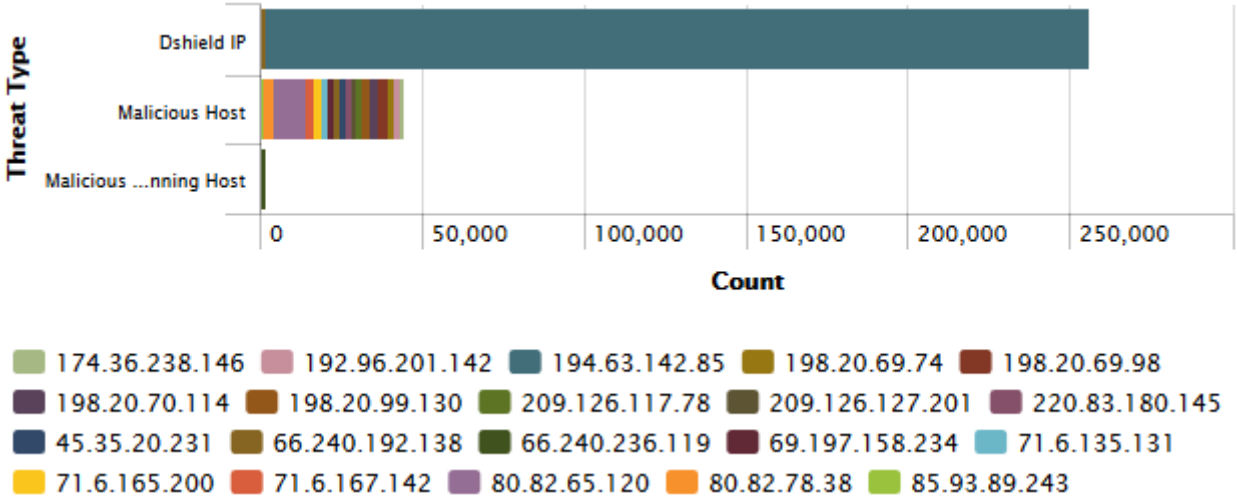


Map of geographic distribution of **124,159** The attacks on METROBANK from known threat sources obtained by correlating values from AlienVault Labs; Emerging Threats; Zeus, Spyeye, and Palevo Tracker. Some results do not include location information that allows map plotting.



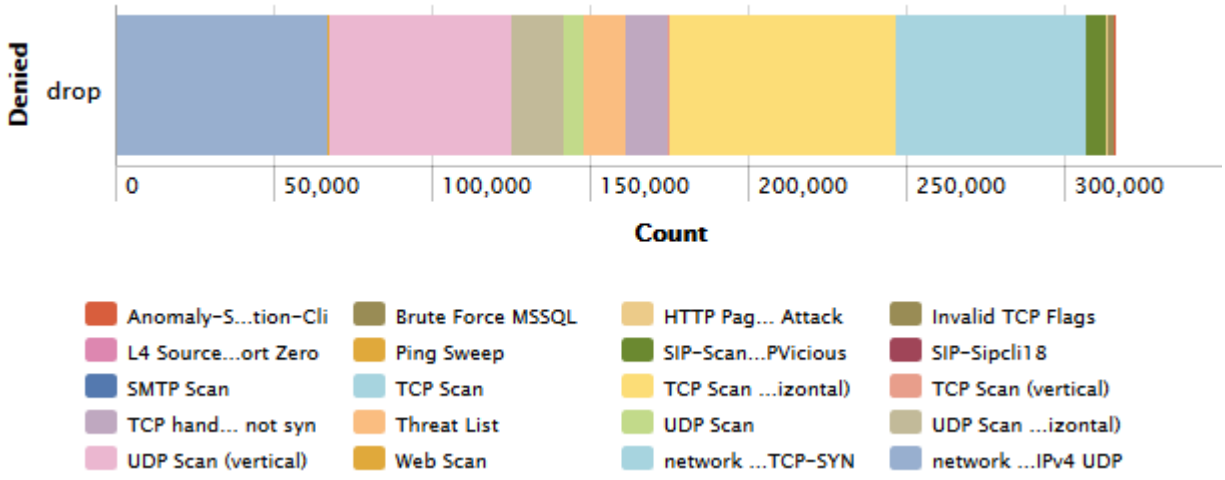
Graph: Known Threat Sources by Threat Type

This report provides the Top 20 known threat sources by IP and their respective infringing threat type.



Graph: Attacks Denied

This report provides the count of total denied attacks along with network security rule.



Port Information

Port Information: Port **80** (http), Port **1443** (ms-sql), Port **8080** (https-alt), Port **3306** (mysql)

Commonly scanned in order to attack web servers. SQL injection is currently the most common form of web site attack in that web forms are very common, often they are not coded properly and the hacking tools used to find weaknesses and take advantage of them are commonly available online. This kind of exploit is easy enough to accomplish that even inexperienced hackers can accomplish mischief. However, in the hands of the very skilled hacker, a web code weakness can reveal root level access of web servers and from there attacks on other networked servers can be accomplished. Structured Query Language (SQL) is the nearly universal language of databases that allows the storage, manipulation, and retrieval of data. Databases that use SQL include MS SQL Server, MySQL, Oracle, PostgreSQL, MongoDB, Access and Filemaker Pro and these databases are equally subject to SQL injection attack.

Web based forms must allow some access to your database to allow entry of data and a response, so this kind of attack bypasses firewalls and endpoint defenses. Any web form, even a simple logon form or search box, might provide access to your data by means of SQL injection if coded incorrectly.

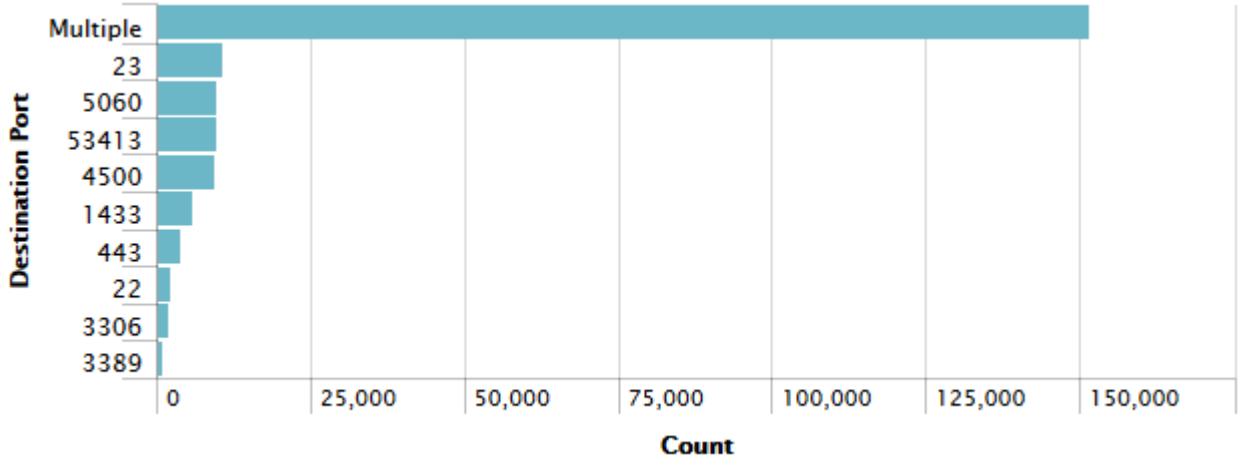
OWASP Top 10 for 2013 lists A1-Injection as the greatest threat and defines this category as:

Injection flaws, such as SQL, OS, and LDAP injection occur when untrusted data is sent to an interpreter as part of a command or query. The attacker's hostile data can trick the interpreter into executing unintended commands or accessing data without proper authorization.

A SQL injection attack consists of insertion or "injection" of a SQL query via the input data from the client to the application. A successful SQL injection exploit can read sensitive data from the database, modify database data (Insert/Update/Delete), execute administration operations on the database (such as shutdown the DBMS), recover the content of a given file present on the DBMS file system and in some cases issue commands to the operating system. SQL injection attacks are a type of injection attack, in which SQL commands are injected into data-plane input in order to effect the execution of predefined SQL commands.

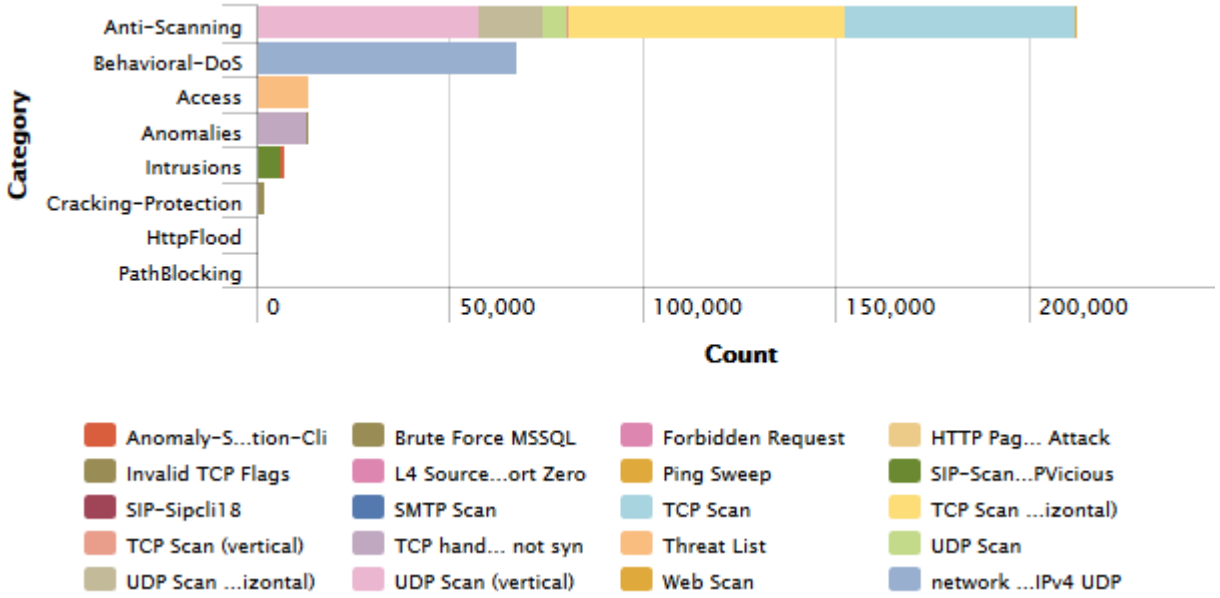
Graph: Attacks Blocked by Destination Port

This report provides information on the total number of attacks blocked that were attempted on which port and for how many times.



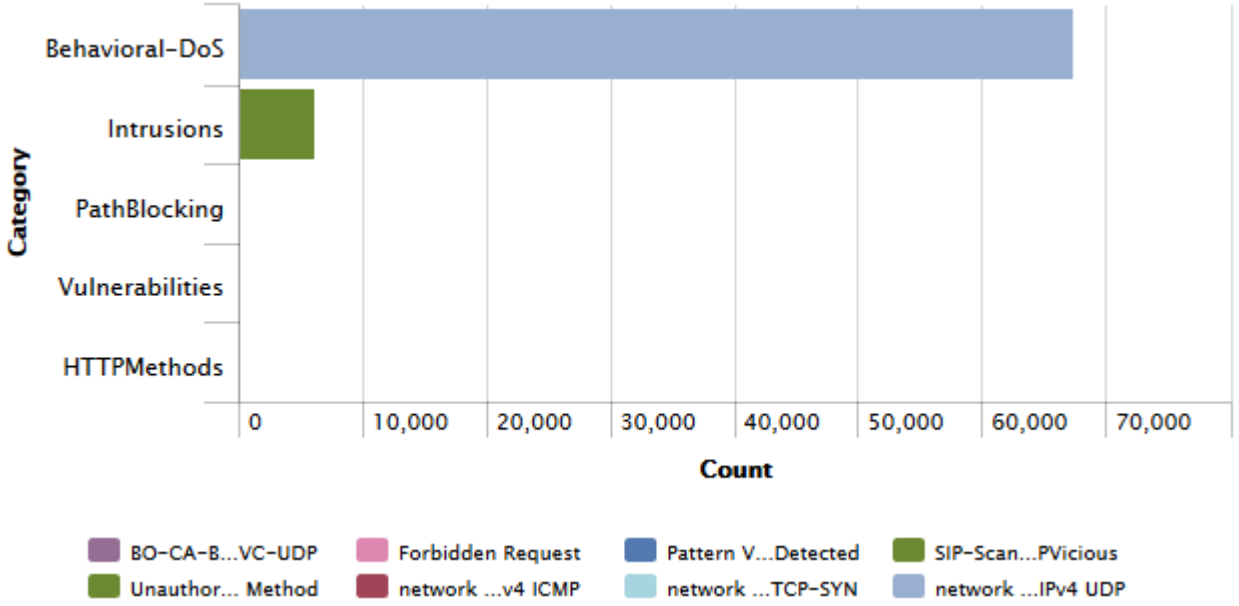
Graph: Attacks Blocked By Threat Category

This report lists the attacks blocked per Attack Category, listing the attack name.



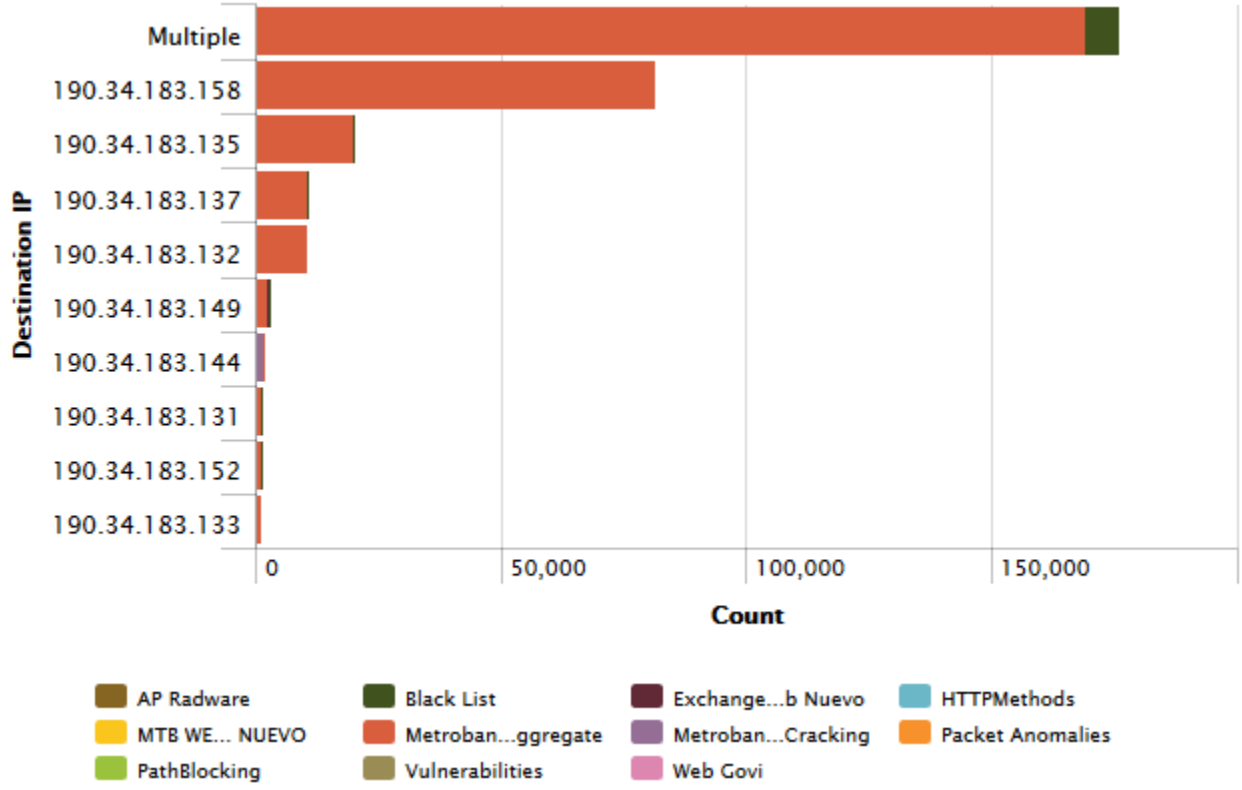
Graph: Critical Attacks Blocked

This report provides Critical Attacks information, attack name, network security rule along with the number of times the attack was launched.



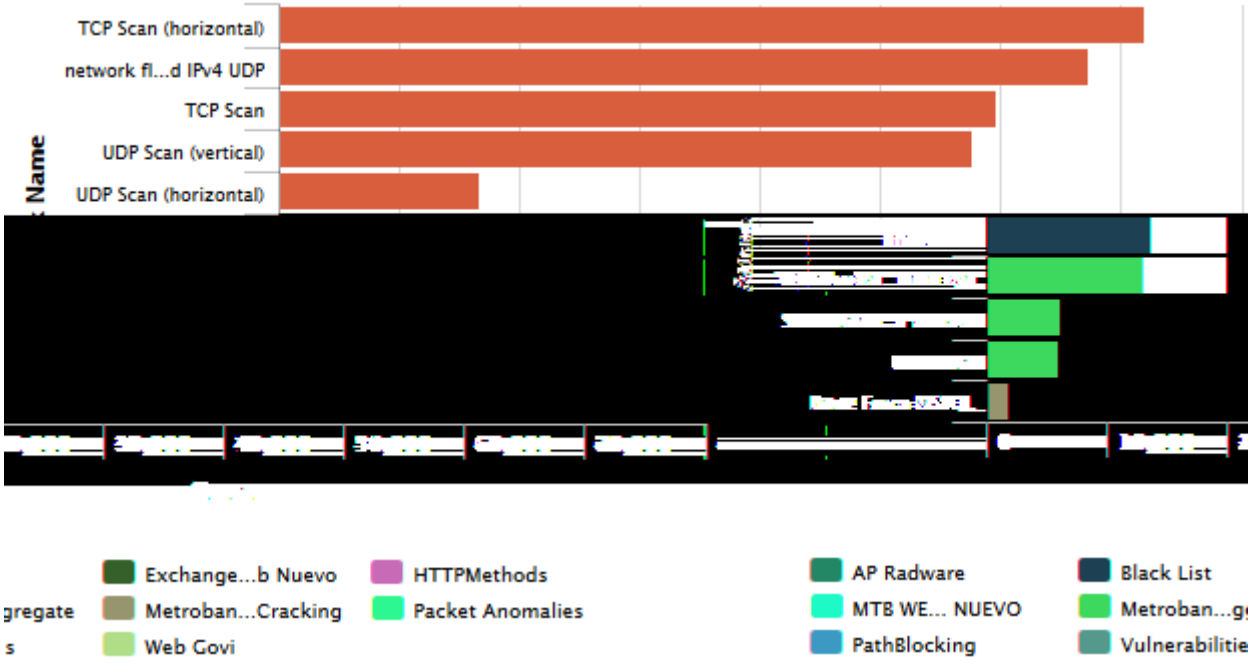
Graph: Top Attacked Destinations Blocked

This report provides information on the system IPs, which were the destination of the attacks for most number of times along with the network security rule.



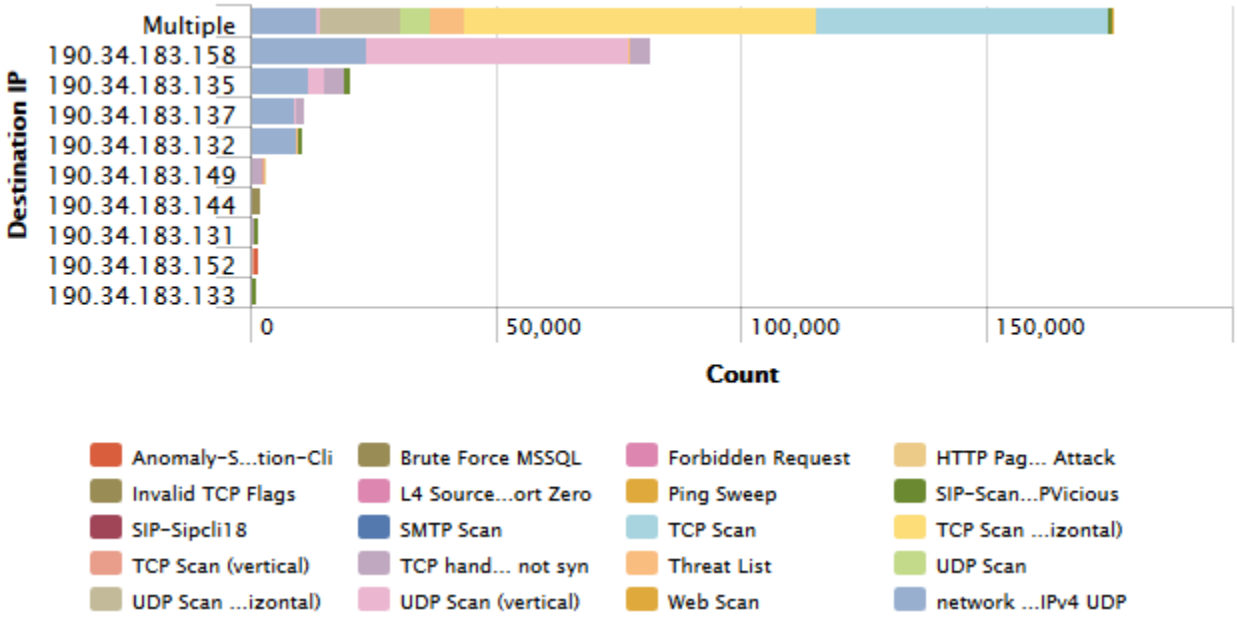
Graph: Top Attacks Blocked

This report provides information on the Top Attacks Blocked, the attack name, network security rule and the total number of attacks blocked with this combination.



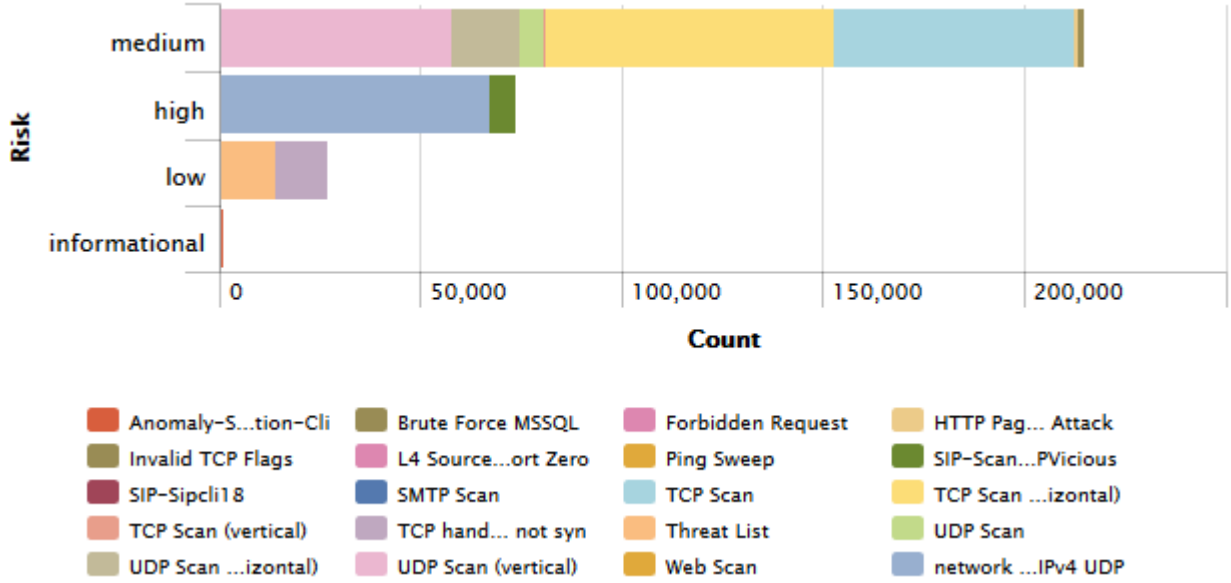
Graph: Top Attacks Blocked by Destination

This report provides information on the top attacks targeted at destinations that were blocked on the DP IPS. In this report the destination on which the attack was targeted, attack name, and count are shown.



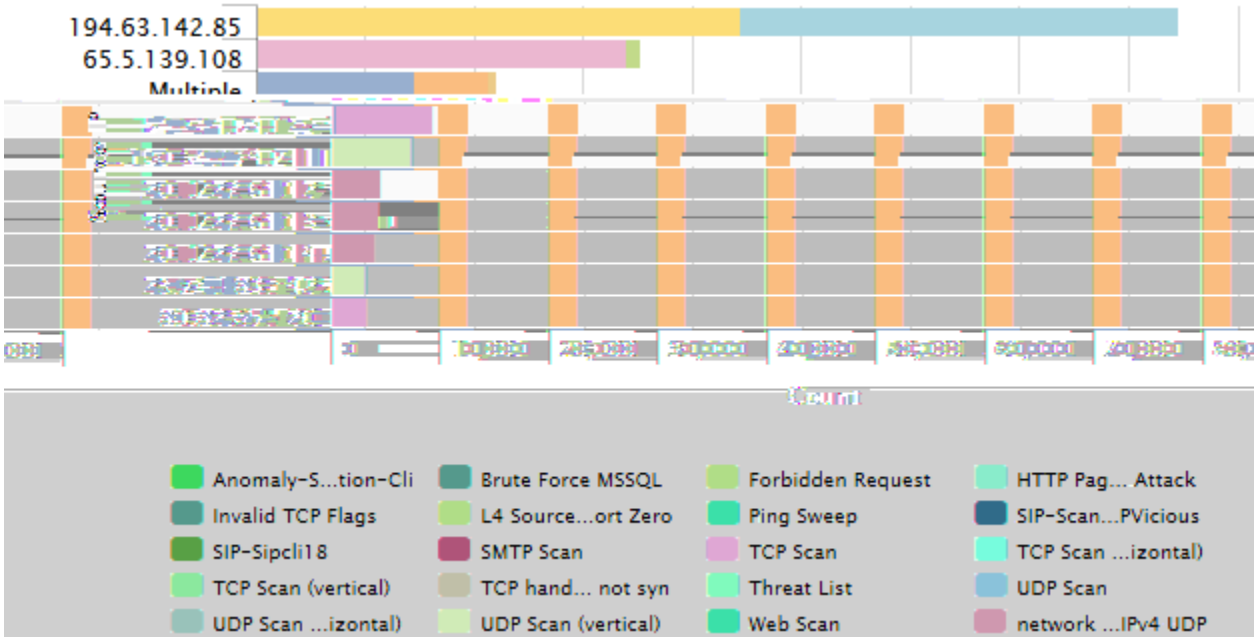
Graph: Top Attacks Blocked By Risk

This report provides information on the attacks, which were blocked on DP IPS based on their risk. In this report the risk of the attack and attack name are shown.



Graph: Top Attacks Blocked by Source

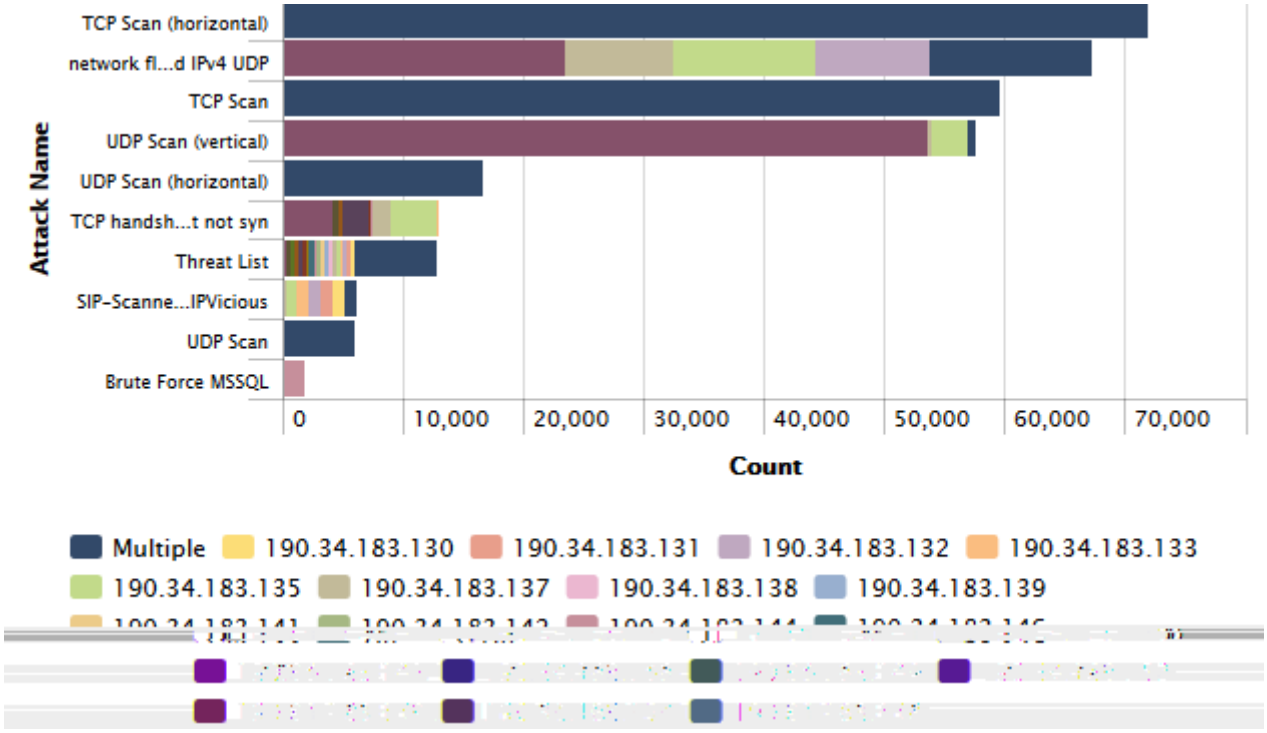
This report provides information on the top attacks blocked, categorized by attacks for each source that was the source of attacks along with the attack name and the number of attacks that triggered with this combination.



NOTE: See Appendix 1 – Critical Attack Sources (WHOIS Information)

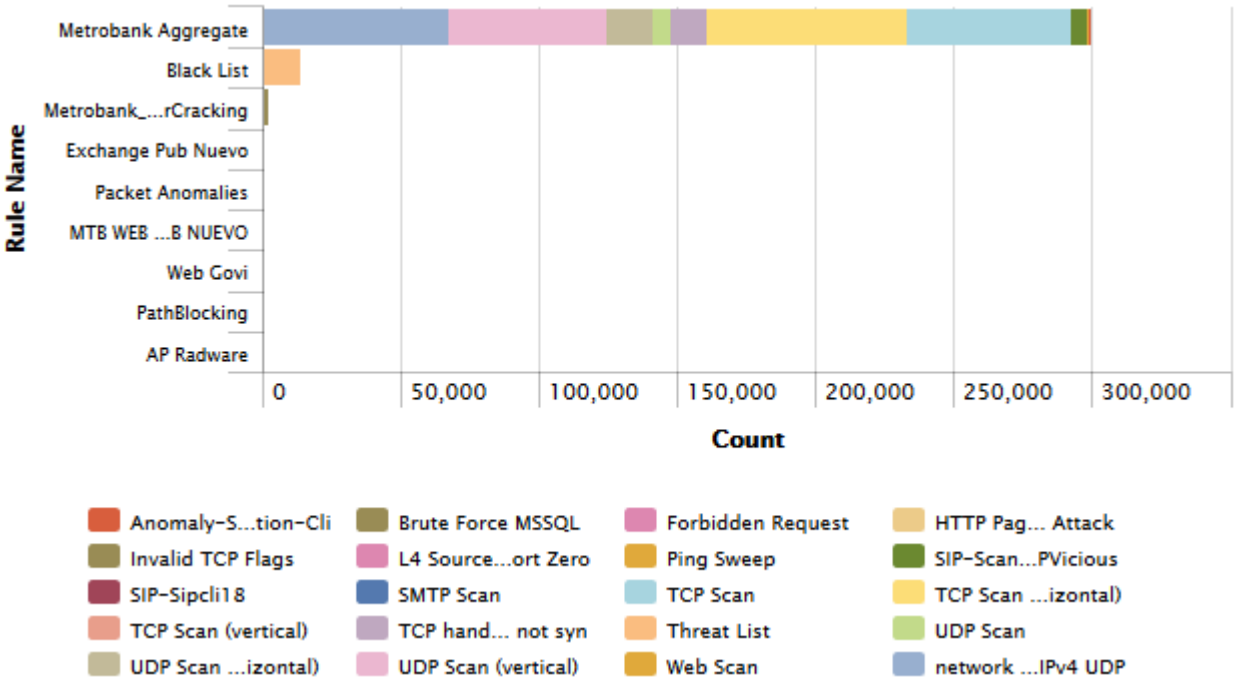
Graph: Top Destinations by Attacks Blocked

This report provides information on the attacks attempted for the most number of times on the destination protected system IPs.



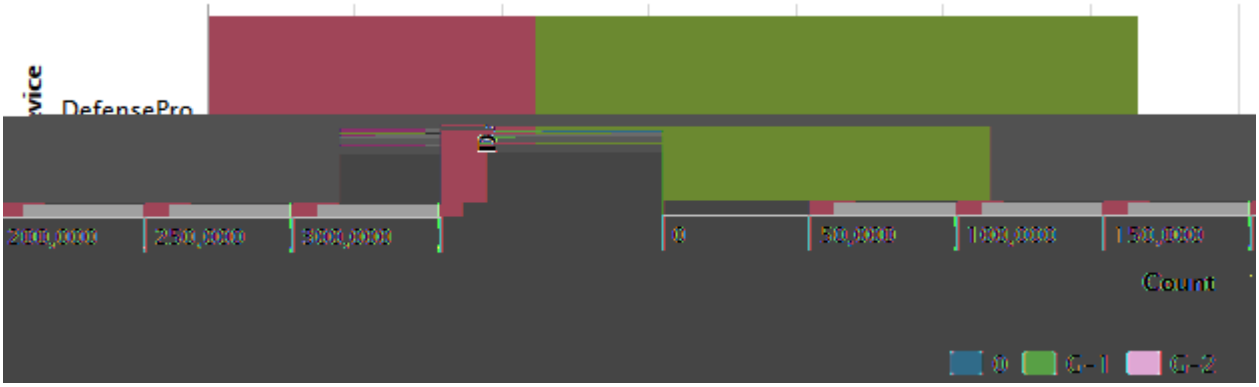
Graph: Attacks Blocked by Network Security Rule

This report lists the attacks per network security rule, listing the attack name.



Graph: Attacks Blocked by Physical Port (per single IPS device)

This report lists the attacks per physical port.



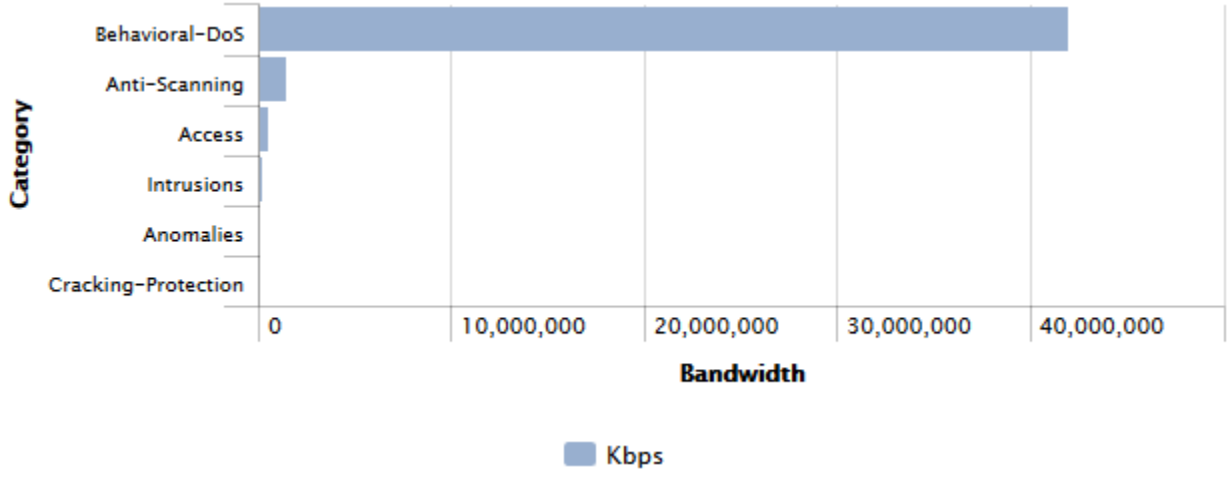
Bandwidth

Behavioral-DoS dropped **40.04 Gbps**, Anti-scanning protection dropped **1.34 Gbps**, Access dropped **0.47 Gbps** of total traffic, **0.23 Gbps** dropped by Intrusion protection rules, Cracking protection dropped **0.01 Gbps** and Packet Anomalies dropped **0.02 Gbps**. A total of **42.11 Gbps** of malicious traffic was discarded this period.

Category	Gbps	Mbps
Behavioral-DoS	40.04	41001.00
Anti-Scanning	1.34	1374.88
Access	0.47	484.17
Intrusions	0.23	234.65
Anomalies	0.02	19.45
Cracking-Protection	0.01	13.18
Total Bandwidth in Gbps/Mbps	42.11	43127.33

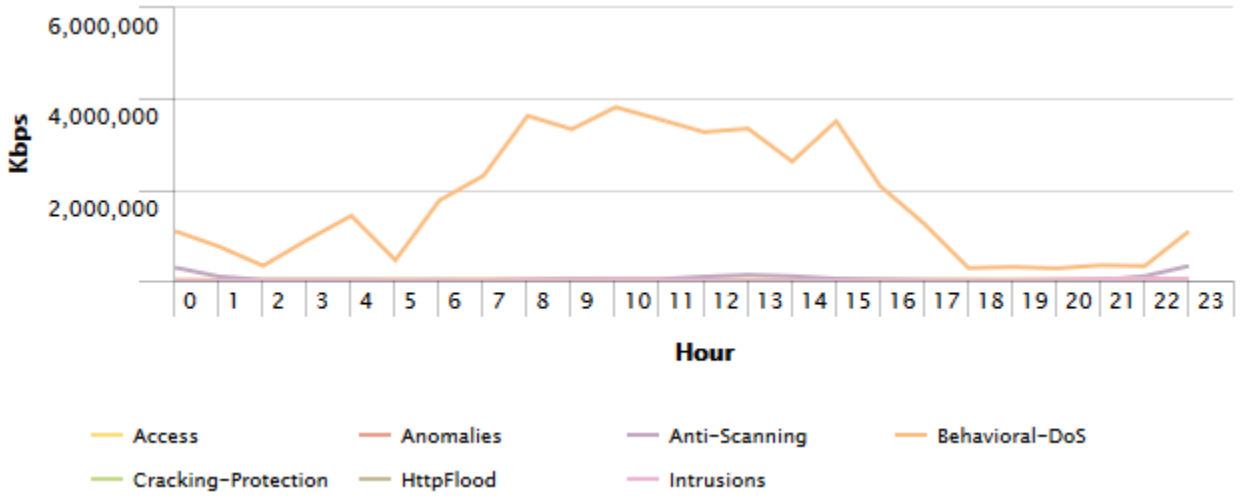
Graph: Attack Categories Blocked by Bandwidth

This report shows the attack categories based on the BW of the attacks sharing the same category including Kbps.



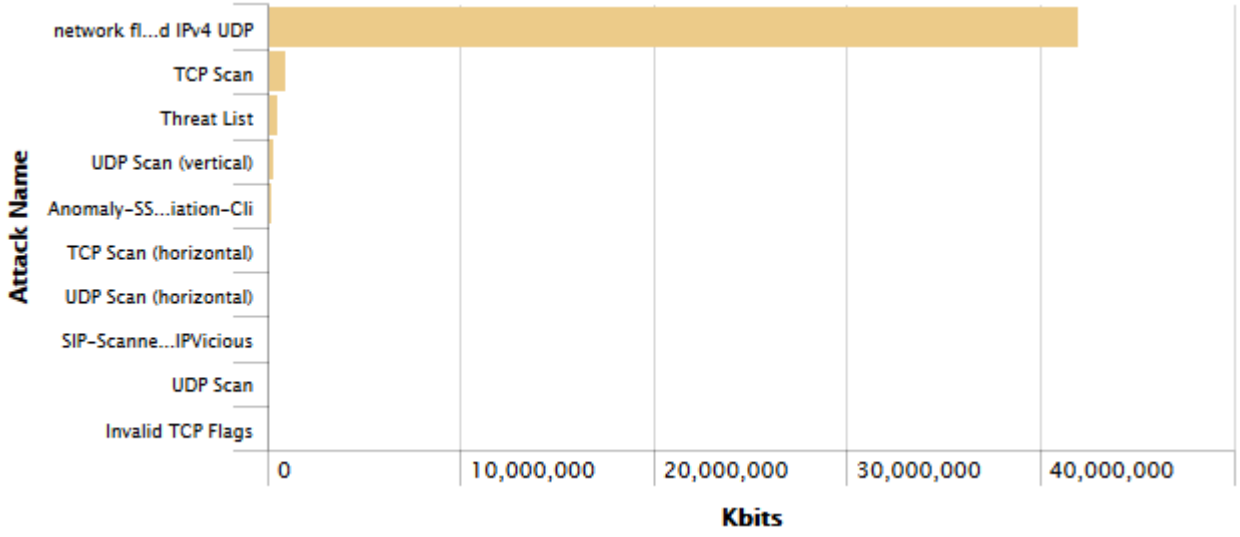
Graph: Bandwidth by Blocked Threat Category by Hour of Day

This report shows the most bandwidth consuming threat categories based on the bandwidth of the attacks sharing the same threat category for each hour of day.



Graph: Top Attacks Blocked by Bandwidth

This report shows the most bandwidth consuming attacks based on the BW of the attack including Kbits.



Scanning Information

Map of geographic distribution of **212,422** attacks on **METROBANK** from scanning sources. Some results do not include location information that allows map plotting.

Network-wide Anti Scanning protections dropped enumeration attempts which otherwise thwart any effort for threat modeling, commonplace after the information gathering phase of a targeted or planned attack.

We have included some of the most important ports scanned this period which tend to be exploited frequently by attackers. **Port Information:** Port **80** (http), Port **443** (http-alt)

Commonly scanned in order to attack web servers. SQL injection is currently the most common form of web site attack in that web forms are very common, often they are not coded properly and the hacking tools used to find weaknesses and take advantage of them are commonly available online. This kind of exploit is easy enough to accomplish that even inexperienced hackers can accomplish mischief. However, in the hands of the very skilled hacker, a web code weakness can reveal root level access of web servers and from there attacks on other networked servers can be accomplished. Structured Query Language (SQL) is

the nearly universal language of databases that allows the storage, manipulation, and retrieval of data. Databases that use SQL include MS SQL Server, MySQL, Oracle, PostgreSQL, MongoDB, Access and Filemaker Pro and these databases are equally subject to SQL injection attack.

Web based forms must allow some access to your database to allow entry of data and a response, so this kind of attack bypasses firewalls and endpoint defenses. Any web form, even a simple logon form or search box, might provide access to your data by means of SQL injection if coded incorrectly.

Port Information: Port **1433** (ms-sql-s), **3306** (mysql)

OWASP Top 10 for 2013 lists A1-Injection as the greatest threat and defines this category as:

Injection flaws, such as SQL, OS, and LDAP injection occur when untrusted data is sent to an interpreter as part of a command or query. The attacker's hostile data can trick the interpreter into executing unintended commands or accessing data without proper authorization.

A SQL injection attack consists of insertion or "injection" of a SQL query via the input data from the client to the application. A successful SQL injection exploit can read sensitive data from the database, modify database data (Insert/Update/Delete), execute administration operations on the database (such as shutdown the DBMS), recover the content of a given file present on the DBMS file system and in some cases issue commands to the operating system. SQL injection attacks are a type of injection attack, in which SQL commands are injected into data-plane input in order to effect the execution of predefined SQL commands.

Port Information: Port **23** (telnet), **22** (ssh)

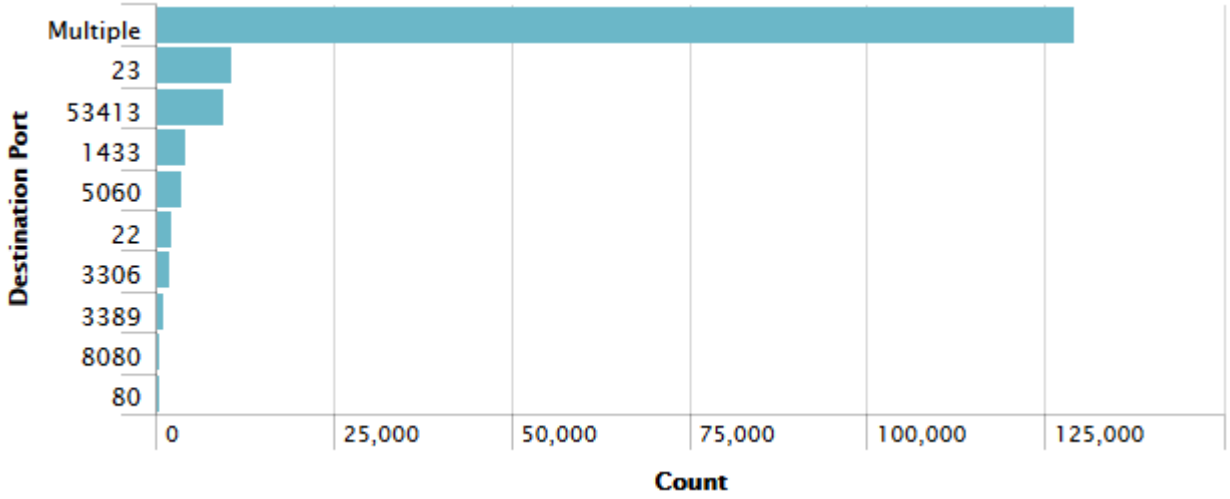
This port is commonly bruteforced for default administrative accounts which usually provide access to network and communications equipment.

Port Information: Port **5060** (sip)

The default gateway commonly associated with the SIP (Session Initiation Protocol) is the system port 5060. This communication portal supports the signaling protocol which is widely deployed for setting up (including tearing down) of sessions involving multimedia communication like video calls, voice calls and even VoIP (Voice over Internet Protocol). Threat actors commonly seek out these servers to comandeer the service in order to make free calls to countries of their choice or use them to carry out phone scams.

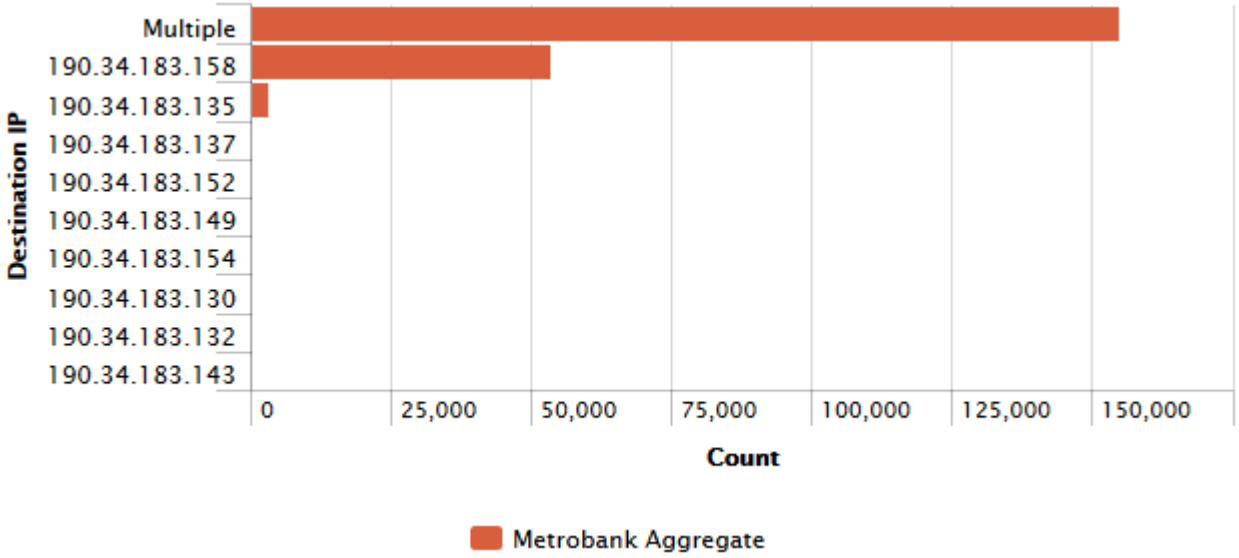
Graph: Top Probed Applications Blocked

This report shows historical view of the Top probed L4 ports.



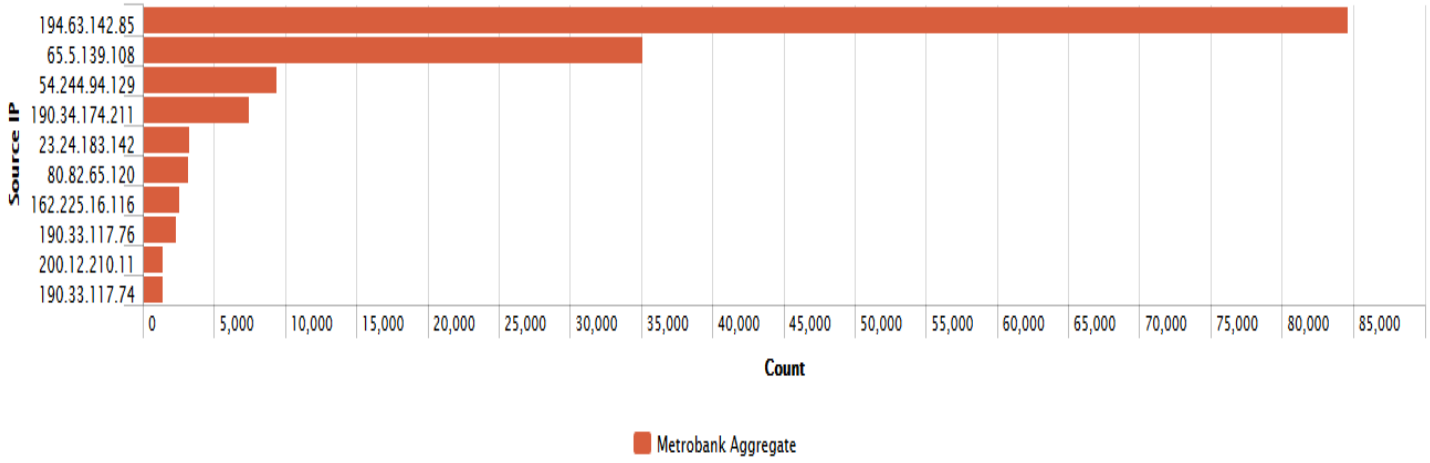
Graph: Top Probed IP Addresses Blocked

This report shows historical view of the Top probed IP addresses that were being scanned along with the network security rule.



Graph: Top Scanners Blocked (Source IP Addressed)

This report shows historical view of the Top source IP addresses that have scanned the network by network scanning activities along with the network security rule.



NOTE: See Appendix 2 – Top Scanners Blocked (Source IP Addressed)

Vulnerability Management

It is important to establish a vulnerability management program as part of the information security strategy because soon after new vulnerabilities are discovered and reported by security researchers or vendors, attackers engineer exploit code and then launch that code against targets of interest. Any significant delays in finding or fixing software with dangerous vulnerabilities provides ample opportunity for persistent attackers to break through, gaining control over the vulnerable machines and getting access to the sensitive data they contain. Organizations that do not scan for vulnerabilities and proactively address discovered flaws face a significant likelihood of having their systems compromised.

The GLESEC AVDS Management System platform performs a security mapping of your organization network, runs tests on everything the speaks IP, and accurately evaluates the presence of vulnerabilities.

Many of the vulnerabilities will provide CVE data. CVE (Common
Vulnerabilities and Exposures) is a list of information security exposures and vulnerabilities sponsored by US-CERT and maintained by the MITRE Corporation. The CVE mission is to provide standard names for all publicly known security exposures as well as standard definitions for security terms. The CVE can be searched online at http://nvd.nist.gov/.

Vulnerability Score

The score of a vulnerability is determined by its risk factor; High, Medium or Low, as well as its value in the Common Vulnerability Scoring System (CVSS). The CVSS "base score" represents the innate risk characteristic of each vulnerability. CVSS is a vulnerability scoring system designed to provide an open and standardized method for rating IT vulnerabilities. CVSS helps organizations prioritize and coordinate a joint response to security vulnerabilities by communicating the base, temporal and environmental properties of each vulnerability. In addition to numeric scores, the CVSS provides severity rankings of High, Medium, and Low but these qualitative rankings are simply mapped from the numeric CVSS scores.

Vulnerabilities are labelled as:

a) Low risk if they have a CVSS base score of 0.0 – 3.9
b) Medium risk if they have a CVSS base score of 4.0 – 6.9
c) High risk if they have a CVSS base score of 7.0 – 10.0

Vulnerabilities in the report are classified into 3 risk categories: high, medium or low.

High Risk

Describes vulnerabilities that can allow an attacker to gain elevated privileges, remote command execution, full read/write access, or critical information disclosure (e.g. passwords, hashes) on a vulnerable machine and should be addressed as top priority.

Medium Risk

Describes vulnerabilities that either expose sensitive data, directory browsing and traversal, disclosure of security controls, facilitate unauthorized use of services or denial of service to an attacker.

Low Risk

Describes vulnerabilities that allow preliminary or sensitive information gathering for an attacker or pose risks that are not entirely security related but maybe used in social-engineering or similar attacks.

Vulnerability Information

We can observe that Intrusions (known attack signatures), HTTP Flood and Web Scanning attempts are targeting Web Servers and are being dropped by the DefensePro. We cannot be 100% sure but there is a high probability that this type of attack is occurring and if the DefensePro was not in place, the attack might have been successfully carried out. The same is true for Mail servers which are frequently being scanned (Web Scanning).

Graph: Risk Distribution

7. Security Operations

The purpose of this section is to highlight the activities performed by GLESEC's Global Operations Center (GOC) including: monitoring availability and performance of equipment under contract, Change Management and Incident Response activities.

a) Monitoring System Availability

METROBANK Appwall Availability:

The Appwall was considered up and available **99.978 %** during this report period.

Host State Breakdowns:

State	Type / Reason	Time	% Total Time	% Known Time
UP	Unscheduled	29d 23h 50m 20s	99.978%	99.978%
	Scheduled	0d 0h 0m 0s	0.000%	0.000%
	Total	29d 23h 50m 20s	99.978%	99.978%
DOWN	Unscheduled	0d 0h 9m 40s	0.022%	0.022%
	Scheduled	0d 0h 0m 0s	0.000%	0.000%
	Total	0d 0h 9m 40s	0.022%	0.022%
UNREACHABLE	Unscheduled	0d 0h 0m 0s	0.000%	0.000%
	Scheduled	0d 0h 0m 0s	0.000%	0.000%
	Total	0d 0h 0m 0s	0.000%	0.000%
Undetermined	Nagios Not Running	0d 0h 0m 0s	0.000%	
	Insufficient Data	0d 0h 0m 0s	0.000%	
	Total	0d 0h 0m 0s	0.000%	
All	Total	30d 0h 0m 0s	100.000%	100.000%

State Breakdowns For Host Services:

Service	% Time OK	% Time Warning	% Time Unknown	% Time Critical	% Time Undetermined
PING	98.854% (98.854%)	0.787% (0.787%)	0.000% (0.000%)	0.359% (0.359%)	0.000%
Average	98.854% (98.854%)	0.787% (0.787%)	0.000% (0.000%)	0.359% (0.359%)	0.000%

METROBANK DefensePro Availability:

The DefensePro was considered up and available **99.997 %** during this report period.

Host State Breakdowns:

State	Type / Reason	Time	% Total Time	% Known Time
UP	Unscheduled	29d 23h 58m 30s	99.997%	99.997%
	Scheduled	0d 0h 0m 0s	0.000%	0.000%
	Total	29d 23h 58m 30s	99.997%	99.997%
DOWN	Unscheduled	0d 0h 1m 30s	0.003%	0.003%
	Scheduled	0d 0h 0m 0s	0.000%	0.000%
	Total	0d 0h 1m 30s	0.003%	0.003%
UNREACHABLE	Unscheduled	0d 0h 0m 0s	0.000%	0.000%
	Scheduled	0d 0h 0m 0s	0.000%	0.000%
	Total	0d 0h 0m 0s	0.000%	0.000%
Undetermined	Nagios Not Running	0d 0h 0m 0s	0.000%	
	Insufficient Data	0d 0h 0m 0s	0.000%	
	Total	0d 0h 0m 0s	0.000%	
All	Total	30d 0h 0m 0s	100.000%	100.000%

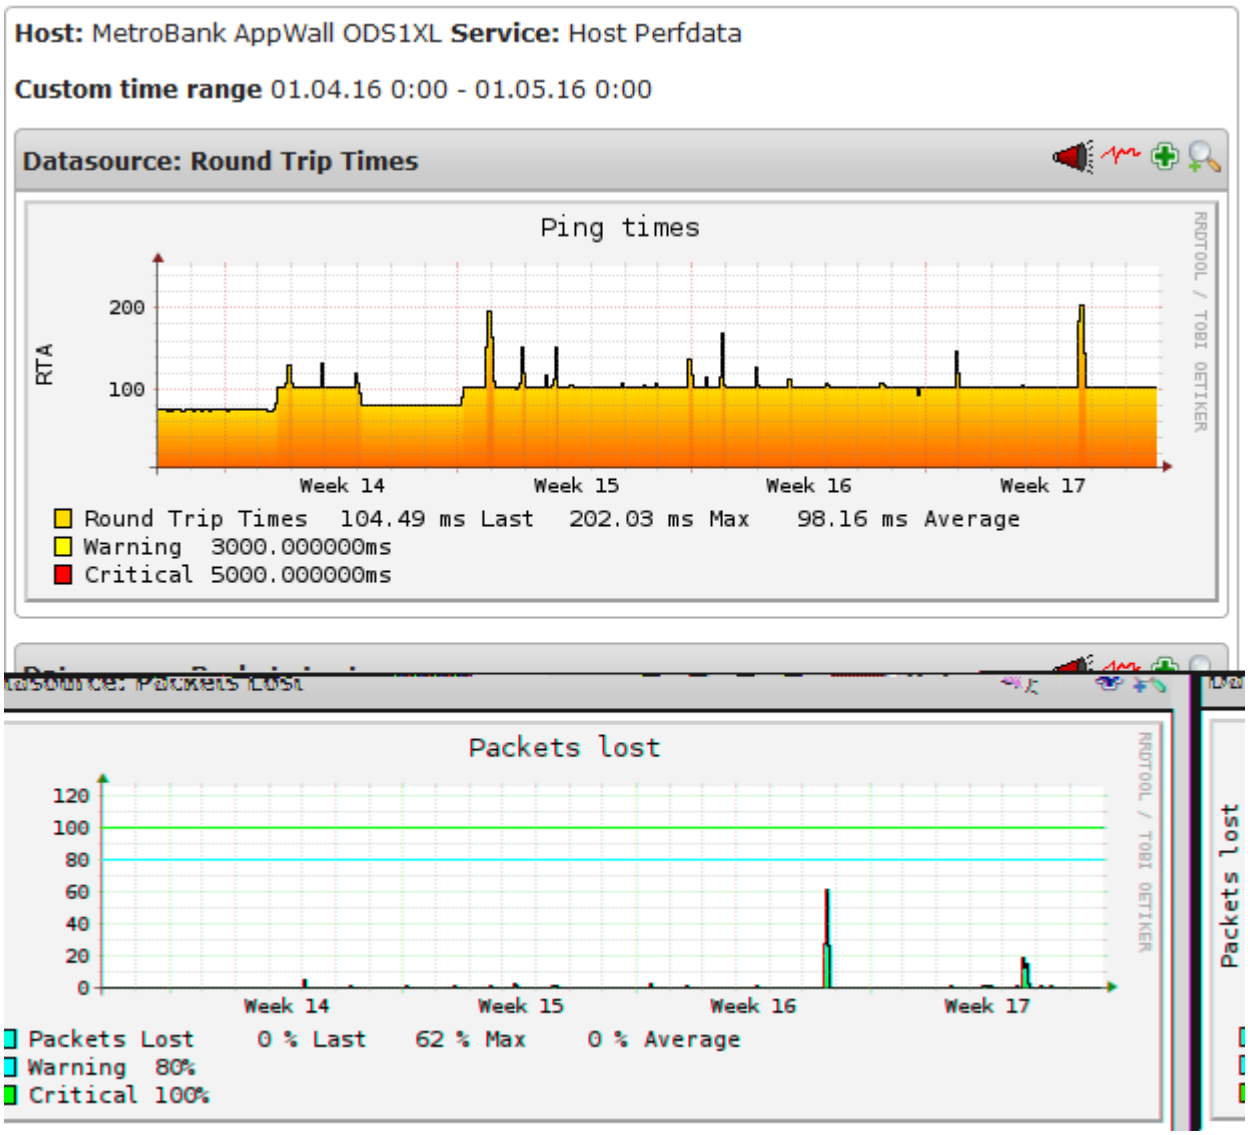
State Breakdowns For Host Services:

Service	% Time OK	% Time Warning	% Time Unknown	% Time Critical	% Time Undetermined
PING	98.796% (98.796%)	0.683% (0.683%)	0.000% (0.000%)	0.521% (0.521%)	0.000%
Average	98.796% (98.796%)	0.683% (0.683%)	0.000% (0.000%)	0.521% (0.521%)	0.000%

b) Monitoring system performance

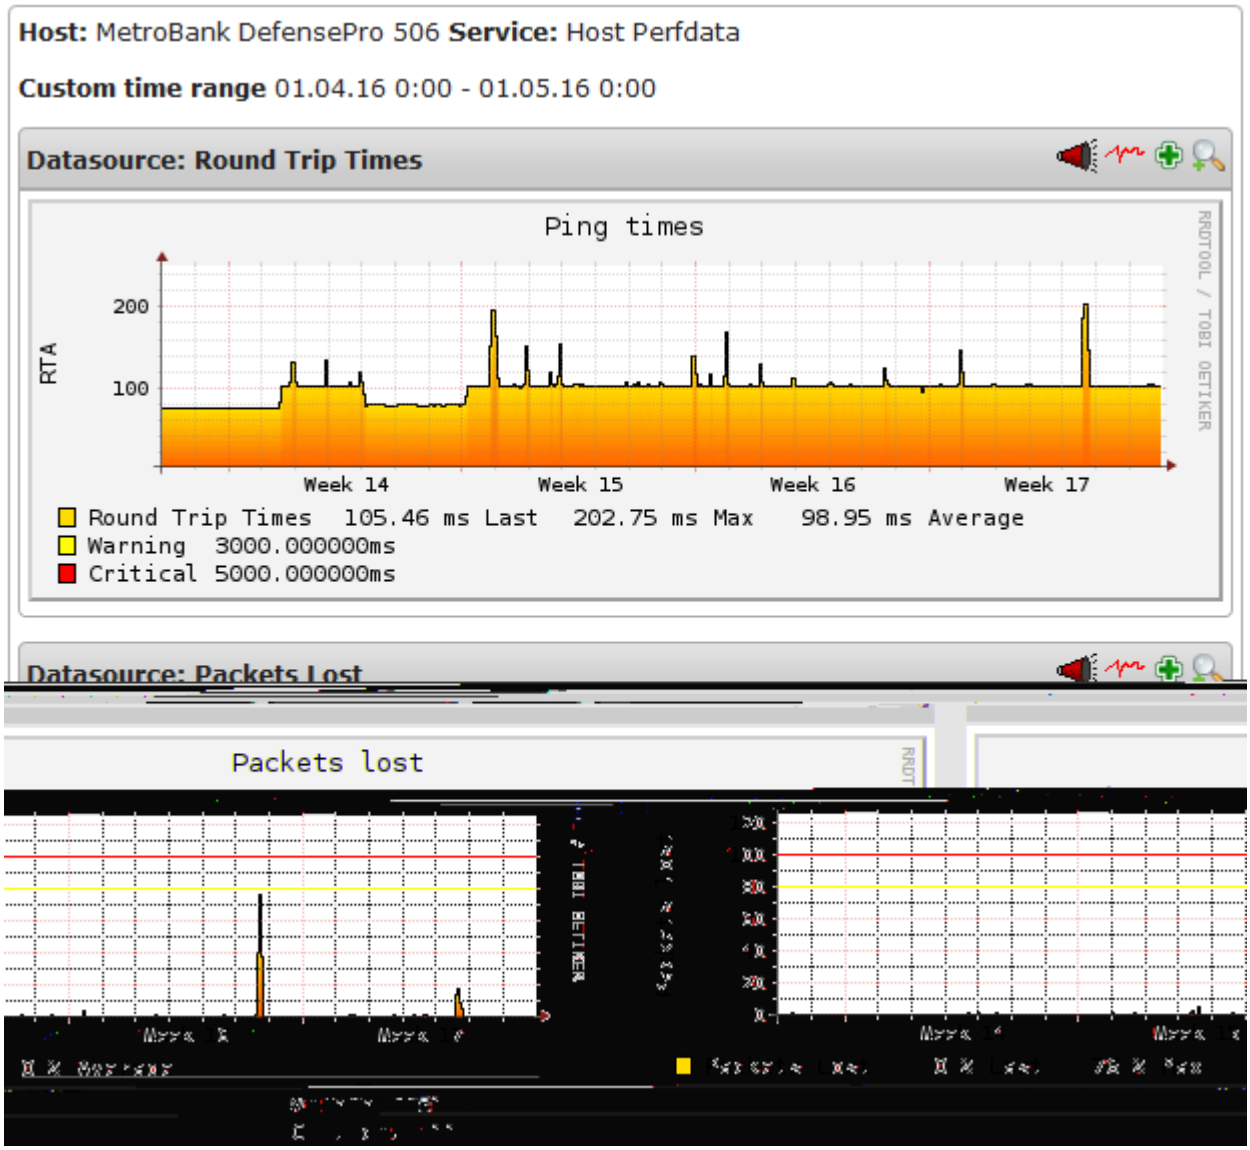
METROBANK Appwall Host Performance

Round trip ping times averaged **98.16** ms from the GLESEC GOC to **METROBANK** with **0 %** average packet loss.



METROBANK DefensePro Host Performance

Round trip ping times averaged **98.95** ms from the GLESEC GOC to **METROBANK** with **0 %** average packet loss.



c) Change Management Procedures

d) Incident Response Procedures

No incident Response activity during the month of April 2016

8. Appendix 1 – Critical Attack Sources (WHOIS Information)

10. Appendix 3 – Glossary of Terms

Amplification Attack

An Amplification Attack is any attack where an attacker is able to use an amplification factor to multiply its power. Amplification attacks are "asymmetric", meaning that a relatively small number or low level of resources is required by an attacker to cause a significantly greater number or higher level of target resources to malfunction or fail. Examples of amplification attacks include Smurf Attacks (ICMP amplification), Fraggle Attacks (UDP amplification), and DNS Amplification.

Botnet

A botnet is a collection of compromised computers often referred to as "zombies" infected with malware that allows an attacker to control them. Botnet owners or "herders" are able to control the machines in their botnet by means of a covert channel such as IRC (Internet Relay Chat), issuing commands to perform malicious activities such as distributed denial-of-service (DDoS) attacks, the sending of spam mail, and information theft. As of 2006, the average size of any given botnet around the world was around 20,000 machines (as botnet owners attempted to scale down their networks to avoid detection), although some larger more advanced botnets such as BredoLab, Conficker, TDL-4, and Zeus have been estimated to contain millions of machines.

Computer Emergency Readiness Team Computer Emergency Response Team Computer Security Incident Response Team

Computer Emergency Response Team is a name given to expert groups that handle computer security incidents. Most groups append the abbreviation CERT or CSIRT to their designation where the latter stands for Computer Security Incident Response Team.

DDoS (Distributed Denial-of-Service) Attack

DDoS or Distributed Denial-of-Service attacks are a variant of Denial-of-Service DoS attacks where an attacker or a group of attackers employ multiple machines to carry out a DoS attack simultaneously, therefore increasing its effectiveness and strength. The "army" carrying out the attack is mostly often composed of innocent infected zombie computers manipulated as bots and being part of a botnet controlled by the attacker via a Command and Control Server. A botnet is powerful, well coordinated and could count millions of computers. It also insures the anonymity of the original attacker since the attack traffic originates from the bots' IPs rather than the attacker's. In some cases, mostly in ideological DDoS attacks, this "army" could also be composed of recruited hackers/hacktivits participating in large DDoS attack

campaigns (Operation Blackout, Operation Payback etc.). DDoS attacks are hard to detect and block since the attack traffic is easily confused with legitimate traffic and difficult to trace.

There are many types of DDoS attacks targeting both the network and the application layers. They could be classified upon their impact on the targeted computing resources (saturating bandwidth, consuming server's resources, exhausting an application) or upon the targeted resources as well:

- Attacks targeting Network Resources: UDP Floods, ICMP Floods, IGMP Floods.
- Attacks targeting Server Resources: the TCP/IP weaknesses –TCP SYN Floods, TCP RST attacks, TCP PSH+ACK attacks – but also Low and Slow attacks as Sockstress for example and SSL-based attacks, which detection is particularly challenging.
- Attacks targeting the Application Resources: HTTP Floods, DNS Floods and other Low and Slow attacks as Slow HTTP GET requests (Slowloris) and Slow HTTP POST requests (R-U-Dead-Yet).

A DDoS attack usually comprises more than three attack vectors thus increasing the attacker's chances to hit its target and escape basic DoS mitigation solutions.

DoS (Denial-of-Service) Attack

A Denial-of-Service DOS attack is an attack targeting the availability of web applications. Unlike other kinds of attacks, DoS attacks' primary goal is not to steal information but to slow or take down a web site. The attackers' motivations are diverse, ranging from simple fun, to financial gain and ideology (hacktivism). A DoS attack generates high or slow rate attack traffic exhausting computing resources of a target, therefore preventing legitimate users from accessing the website. DoS attacks affect enterprises from all sectors (e-gaming, Banking, Government etc.), all sizes (mid/big enterprises) and all locations. They target the network layer and up to the application layer, where attacks are more difficult to detect since they could easily get confused with legitimate traffic. There are several types of DoS attacks. A (non-distributed) DoS attack is when an attacker uses a single machine's resources to exhaust those of another machine, in order to prevent it from functioning normally. Large Web servers are usually robust enough to withstand a basic DoS attack from a single machine without suffering performance loss. A DoS attack famous variant is the DDoS or Distributed Denial of Service attack where the attack originates from multiple computers simultaneously, therefore causing the victim's resources exhaustion.

DNS Amplification Attack

DNS amplification attack is a sophisticated denial of service attack that takes advantage of DNS servers' behavior in order to amplify the attack. In order to launch a DNS amplification

exploit targeting the latest version of Apple's mobile operating system, iOS, might fetch $100,000 or more.

Flood

"Flood" is the generic term for a denial-of-service (DoS) attack in which the attacker attempts to constantly send traffic (often high volume of traffic) to a target server in an attempt to prevent legitimate users from accessing it by consuming its resources. Types of floods include (but are not limited to): HTTP floods, ICMP floods, SYN floods, and UDP floods.

Hacker

The term "hacker" has been used to mean various things in the world of computing: one who is able to subvert computer security (regardless of intentions), one who is a member of the open-source software community and subculture, and one who attempts to push the limits of computer software and hardware through home modifications. In the world of computer security, the term "hacker" is often portrayed as negative by mass media, despite the prevalence of "white hat hacking", or ethical hacking for the purpose of discovering potential security flaws and reporting them to the proper individuals or organizations so that the flaws may be patched. Black hat hacking, on the other hand, is the breaking into computer systems without any intention of reporting discovered vulnerabilities, often with malicious or financial incentives. The hackers who fall somewhere on the spectrum between "white hats" and "black hats" are referred to as "grey hats". Grey hat hackers will often perform mischievous activities with (usually non-malicious although at times questionably ethical) motivations. Additionally, grey hat hackers often choose not to report security flaws to the proper channels; rather, they report such information to the hacking community and the general public, enjoy watching the fallout as those with the security flaws scramble to fix them before they can be abused by black hat hackers. Within the open-source software and computer hobbyist communities, however, "hacker" usually has a less negative connotation. Within these cultures, hackers are often individuals regarded as intelligent and clever, and able to come up with creative solutions to existing problems that a software or hardware product developer may have not thought of or publicly released yet. These hackers often refer to "hackers" within the computer security world as "crackers" (as in safe-cracker) to emphasize their belief that calling such individuals "hackers" is incorrect. With the rise of hacker and "hacktivist" groups such as LulzSec (now LulzSec Reborn) and Anonymous, the mass media portrayal of the term "hacker" continues to lead the general public to believe "hacker" is synonymous with "cybercriminal".

Hacktivist

"Hacktivist", a portmanteau of "hack" and "activism", was a term coined in 1996 by Omega, a member of the hacking coalition "Cult of the Dead Crow" (cDc). The term can be loosely defined as, "the ethically ambiguous use of computers and computer networks in order to affect the normal operation of other systems, motivated by a desire to protest or promote political ends."Oftentimes these events take the form of web site defacements, denial-of-service attacks, information theft, web site parodies, virtual sit-ins, typo squatting, and virtual sabotage. The term has become popular among media outlets in recent years due to the rise of various politically motivated cyber attacks by groups such as Anonymous and LulzSec (now LulzSec Reborn) on governments and corporations across the world.

Honeypot

In computer security, a honeypot is a program or a server voluntarily made vulnerable in order to attract and lure hackers. The attackers who think they are targeting a real resource behave "normally", using their attack techniques and tools against this lure site, which allow the defenders to observe and monitor their activities, analyze their attacking methods, learn and prepare the adequate defenses for the real resources. There are several kinds of honeypots, some used for research purposes only while others are actively acting as defenses for the real sites.

HTTP Flood

An HTTP flood is an attack method used by hackers to attack web servers and applications. It consists of seemingly legitimate session-based sets of HTTP GET or POST requests sent to a target web server. These requests are specifically designed to consume a significant amount of the server's resources, and therefore can result in a denial-of-service condition (without necessarily requiring a high rate of network traffic). Such requests are often sent en masse by means of a botnet, increasing the attack's overall power. HTTP flood attacks may be one of the most advanced non-vulnerability threats facing web servers today. It is very hard for network security devices to distinguish between legitimate HTTP traffic and malicious HTTP traffic, and if not handled correctly, it could cause a high number of false-positive detections. Rate-based detection engines are also not successful at detecting HTTP flood attacks, as the traffic volume of HTTP floods may be under detection thresholds. Because of this, it is necessary to use several parameters detection including rate-based and rate-invariant.

I2P

I2P is an anonymous overlay network - a network within a network. It is intended to protect communication from dragnet surveillance and monitoring by third parties such as ISPs.

ICMP Flood

Internet Control Message Protocol (ICMP) is a connectionless protocol used for IP operations, diagnostics, and errors. An ICMP Flood - the sending of an abnormally large number of ICMP packets of any type (especially network latency testing “ping” packets) - can overwhelm a target server that attempts to process every incoming ICMP request, and this can result in a denial-of-service condition for the target server.

Internet pipe saturation

These attacks are volumetric floods and often involve flooding the target with an overwhelming bandwidth. Common attacks utilize UDP as it is easily spoofed and difficult to mitigate downstream. Out of state, SYN floods and malformed packets are also often seen. While many attacks aim at saturating inbound bandwidth, it’s not uncommon for attackers to identify and pull large files from websites, ftp shares, etc. in order to saturate outbound bandwidth as well.

IP Address

An IP address is an identifier for a device connected to a network using TCP/IP - a protocol that routes network traffic based on the IP address of its destination. IP addresses can either be 32-bit IPv4 addresses consisting of four base-10 numbers separated by periods representing eight digit binary (base-2) numbers called “octets” (i.e. 0.0.0.0 to 255.255.255.255), or 128-bit IPv6 addresses consisting of eight hexadecimal (base-16) numbers separated by colons representing sixteen digit binary (base-2) numbers (i.e. 0000:0000:0000:0000:0000:0000:0000:0000 to FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF:FFFF where consecutive groups of four zeroes are replaced by a double colon). When the Internet first became popular, IPv4, with its 32-bit addresses, offered 232, or roughly 4.3 x 109 unique addresses. As the number of Internet-connected devices began to grow significantly, people worried that the IPv4 protocol would not contain enough addresses to meet the growing demand for new unique addresses this is why IPv4 will eventually be replaced by IPv6 on a large scale (IPv6 already officially launched in August 2012), which contains 2128 or roughly 3.4 x 1038 unique addresses. The Dynamic Host Configuration Protocol (DHCP), which runs on special devices (usually routers) allows for the assigning of IP addresses within a local area network (LAN). DHCP assigns IP addresses on a temporary “lease” basis; once a device’s IP address lease expires, a DHCP server will assign it a new (potentially different) one. IP addresses automatically assigned by a DHCP server are therefore referred to as “dynamic IP addresses”, as a device with a DHCP-assigned IP address may eventually receive an IP different from its original one.

DHCP servers will not assign devices just any IP address in the maximum range of IPv4 addresses (0.0.0.0 to 255.255.255.255), as certain IP addresses are reserved for special purposes. Such addresses include:

- 0.0.0.0 – Represents the "default" network, i.e. any connection
  255.255.255.255 – Represents the broadcast address, or place to route messages to be sent to every device within a network
- 127.0.0.1 – Represents "localhost" or the "loopback address", allowing a device to refer to itself, regardless of what network it is connected to
- 169.254.X.X – Represents a "self-assigned IP address", which a device will assign itself if it is unable to receive an IP address from a DHCP server

Users' DHCP-assigned IP addresses on a LAN are not the same as their "external" or Internet IP address. This address will be the same for all users connected to a DHCP server, which itself receives an IP address from the Internet Service Provider (ISP) it is connected to. As IP addresses can be used as unique identifiers for users' machines (and subsequently the users themselves), knowledge of a malicious user's external Internet IP address can allow law enforcement officials to block, locate, and eventually arrest him or her. As a result, the more advanced attack tools and hackers will employ anonymization techniques - such as the use of proxy servers, VPNs, or a routing network like Tor or I2P - that can make it seem like they are using a different IP address other than their own, located somewhere else in the world. An attack tool called Low Orbit Ion Cannon (LOIC) became infamous for not hiding its users' IP addresses; this resulted in the arrest of various LOIC users around the world for their participation in distributed denial-of-service (DDoS) attacks.

IP Spoofing

IP Spoofing is the act of creating an IP packet with a forged source IP address for the purpose of hiding the true source IP address, usually for the purpose of launching special types of distributed denial-of-service (DDoS attacks). By forging the source IP address of a packet; the individual sending it can direct the target IP address' machine to send its reply packet somewhere other than the real IP address of the source machine. Those wishing to launch DDoS attacks without large botnets can therefore send packets with random spoofed source IP addresses in order to both conceal their own identity and make the attack harder to block (as it looks like it is originating from many sources).

IRC (Internet Relay Chat)

IRC (Internet Relay Chat) is a protocol for real-time text messaging between internet-connected computers created in 1988. It is mainly used for group discussion in chat rooms called "channels" although it supports private messages between two users, data transfer,

a

MSSP

An MSSP (Managed Security Service Provider) is an organization which provides "Security as a Service" (Sec-aaS) and may include elaborate operations such as SOCs and NOCs, or something as simple as a cloud-based key management service. Generally speaking, an MSSP is considered an outsourced operation of what was an internal security device or process management function.

Network scan

Scanning is typically an automated process that is used to discover devices such as pc, server and peripherals that exist on a network. Results can include details of the discovered devices, including IP addresses, device names, operating systems, running applications/services, open shares, usernames and groups. Scanning is often related to pre -attack or reconnaissance activities. There are two types of scanning: Horizontal Scan in which the scanner scans for the same port on multiple IPs, and Vertical Scan in which the scanner scans multiple ports on one IP.

Packet

A packet is a formatted unit of data used to transmit information piece by piece across a packet switched network. Packets usually contain three sections: a header, the payload, and a trailer (also called “footer”). A packet header contains information such as the length of the packet (if the network does not use a predetermined fixed packet size), synchronization bits to help the packet match up with the network, a packet number to differentiate each packet from the others, the protocol (i.e. type of information contained within the packet), and the source and destination IP addresses. The “payload” of a packet contains the actual information being transmitted. The trailer or “footer” usually contains a series of bits signaling to the receiving device that it has reached the end of the packet, as well as some type of error-checking information to ensure that the packet was not modified in transit.

Port Scan

A port scanner is a technical leverage to identify available technical services (ports) on a server or application and may include logic to evaluate whether or not those services are vulnerable to common exploits or configuration issues. This is done by sending predetermined traffic to the target and based on a response or lack of a response, the port scanner in use makes its own conclusions with regards to the functionality of the port being scanned.

Reflector/Reflective DoS attacks

Reflection Denial of Service attacks makes use of a potentially legitimate third party component to send the attack traffic to a victim, ultimately hiding the attackers' own identity. The attackers send packets to the reflector servers with a source IP address set to their victim's IP therefore indirectly overwhelming the victim with the response packets.

The reflector servers used for this purpose could be ordinary servers not obviously compromised, which makes this kind of attack particularly difficult to mitigate. A common example for this type of attack is Reflective DNS Response attack.

SIP Brute Force

SIP brute force is an adaptation of normal brute force attacks which attack SIP servers and attempt access to servers to make unauthorized outbound calls at another's expense.

SIP Client Call Flood

This is a flood technique focused on SIP application protocol which involves illegitimate call requests. The idea here is to flood the Session Boarder Control (SBC) and / or SIP / VOIP PBX with too many requests to handle and thus making the service unavailable.

SIP Malformed Attack

Scrubbing Center

A centralized data cleansing station where traffic is analyzed and malicious traffic (ddos, known vulnerabilities and exploits) is removed. Scrubbing centers are often used in large enterprises, such as ISP and Cloud providers, as they often prefer to off-ramp traffic to an out of path centralized data cleansing station. When under attack, the traffic is redirected (typically using DNS or BGP) to the scrubbing center where an attack mitigation system mitigates the attack traffic and passes clean traffic back to the network for delivery. The scrubbing center should be equipped to sustain high volumetric floods at the network and application layers, low and slow attacks, RFC Compliance checks, known vulnerabilities and zero day anomalies.

Social Engineering

Social Engineering (within the context of computer security) is the act of using psychological manipulation in order to gain access to sensitive information, computers, or computer networks. Many famous computer hackers (both white hat and black hat) have used social engineering in combination with computer-related methods in order to gain information; reformed cyber criminal Kevin Mitnick admitted that it's much easier to trick a person into giving up sensitive passwords or information than it is to obtain the same material solely through the use of computers. One example of a social engineering technique is "pretexting", or engaging the target subject in a specific manner with some form of background information that makes it more likely that he or she will divulge sensitive information. Pretexting often involves extensive research, as the social engineer will need to prepare answers to identifying questions that he or she may be asked during the process of obtaining information. This newly obtained information can often be used in further pretexting attempts, especially in scenarios where the social engineer wishes to gain even greater access to his or her target.

SQL Injection

SQL injection is an attack targeting web applications taking advantage of poor application coding where the inputs are not sanitized therefore exposing application vulnerabilities. SQL injection is the most famous type of injection attacks which also count LDAP or XML injections. The idea behind a sql injection is to modify an application SQL (database language) query in order to access or modify unauthorized data or run malicious programs. Most web applications indeed rely on databases where the application data is stored and being accessed by SQL queries and modifications of these queries could mean taking control of the application. An attacker would for example be able to access the application database with administrator access, run remote commands on the server, drop or create objects in the database and more.

For instance, the sql query below, aiming at authenticating users, is common in web applications:

- myQuery= ”SELECT * FROM userstable WHERE username = 'userinput1' and password ='userinput2';”
- Replacing userinput1 by: ‘OR 1=1’); -- would result in granting the attacker access to the database without knowing the real username and password as the assertion “1=1” is always true and the rest of the query is being ignored by the comment character (- - in our case).
- Replacing the userinput1 by ' OR 1=1"); drop table users;-- would additionally drop the application users table.

SYN Flood

A SYN flood is a denial-of-service (DoS) attack that relies on abusing the standard way that a TCP connection is established. Typically, a client sends a SYN packet to an open port on a server asking for a TCP connection. The server then acknowledges the connection by sending SYN-ACK packet back to the client and populating the client’s information in its Transmission Control Block (TCB) table. The client then responds to the server with an ACK packet establishing the connection. This process is commonly known as a “three-way handshake”. A SYN flood overwhelms a target machine by sending thousands of connection requests to it using spoofed IP addresses. This causes the target machine to attempt to open a connection for each malicious request and subsequently wait for an ACK packet that never arrives. A server under a SYN flood attack will continue to wait for a SYN-ACK packet for each connection request, as the delay could be normal and related to network congestion. However, because a SYN-ACK packet never arrives for any of the connection requests; the massive number of half-open connections quickly fills up the server’s TCB table before it can time any connections out. This process continues for as long as the flood attack continues. Attackers will sometimes add legitimate information to their requests as well, such as sequence number or source port 0, as this increases a target server’s CPU usage on top of causing network congestion, and could more effectively cause a denial-of-service condition.

TCP Flood

TCP SYN floods are one of the oldest yet still very popular Denial of Service (DoS) attacks. The most common attack involves sending numerous SYN packets to the victim. The attack in many cases will spoof the SRC IP meaning that the reply (SYN+ACK packet) will not come back to it. The intention of this attack is overwhelm the session/connection tables of the targeted server or one of the network entities on the way (typically the firewall). Servers need to open a state for each SYN packet that arrives and they store this state in tables that have limited

size. As big as this table may be it is easy to send sufficient amount of SYN packets that will fill the table, and once this happens the server starts to drop a new request, including legitimate ones. Similar effects can happen on a firewall which also has to process and invest in each SYN packet. Unlike other TCP or application level attacks the attacker does not have to use a real IP; this is perhaps the biggest strength of the attack.

Tor

Tor is a network of virtual tunnels that allows people and groups to improve their privacy and security on the Internet. It also enables software developers to create new communication tools with built-in privacy features. Tor provides the foundation for a range of applications that allow organizations and individuals to share information over public networks without compromising their privacy.

UDP Flood

A UDP flood is a network flood and still one of the most common floods today. The attacker sends UDP packets, typically large ones, to single destination or to random ports. In most cases the attackers spoof the SRC IP which is easy to do since the UDP protocol is "connectionless" and does not have any type of handshake mechanism or session. The main intention of a UDP flood is to saturate the Internet pipe. Another impact of this attack is on the network and security elements on the way to the target server, and most typically the firewalls. Firewalls open a state for each UDP packet and will be overwhelmed by the UDP flood connections very fast.

Vulnerability

A vulnerability (in computer security) is any weakness in a computer system, network, software, or any device that allows one to circumvent security measures and perform actions not intended by its developers or manufacturers. Vulnerabilities range from minor to major, with the most significant allowing for privilege escalation (unauthorized administrator or root privileges) or code execution (the running of unsigned 3rd party software). New vulnerabilities can often be discovered by the process of "fuzzing", or purposely trying to break something by attempting to give it unreasonable input values. Once some kind of crash occurs and can be analyzed, one can discover the existence of a vulnerability that may have not been previously documented. Previously unknown vulnerabilities, known as "Zero-Day" vulnerabilities are highly sought after by hackers and developers and manufacturers alike. By using an exploit based on zero-day vulnerability, a hacker can guarantee that his or her attempt to break into a particular computer or device that possesses such vulnerability will succeed. Zero-day exploits are traded on both the black market and through legitimate middlemen between parties for anywhere from $5,000 to $250,000 depending on the effects

of the exploit and which system they target. Where a PDF exploit might only fetch a few thousand dollars, a severe exploit targeting the latest version of Apple's mobile operating system, iOS, might fetch $100,000 or more.

Vulnerability Scanner

A vulnerability scanner is a type of computer program used to gather information on computers and systems on a network in order to find their weaknesses. By using a vulnerability scanner tool such as nmap or unicornscan, one can determine the number of clients attached to a particular network as well as various information regarding their addresses, ports, applications and services and potential exploits that can be used against them. Some scanners offer the ability to deploy payloads for the purpose of using a found exploit, and others simply display information on network topology. Types of vulnerability scanners include: port scanners, network enumerators, network vulnerability scanners, web application security scanners, database security scanners, ERP security scanners, and computer worms (which require scanning capabilities to spread within a network).

Wireshark

Wireshark is a free cross-platform open-source network traffic capture and analysis utility. It began as a project called "Ethereal" in the late 1990s, but its name was changed to "Wireshark" in 2006 due to trademark issues. The initial code was written by Gerald Combs, a computer science graduate of the University of Missouri-Kansas City, today the Wireshark website now lists over 600 contributors. The program is GUI-based and uses pcap to capture packets, although there is also a command-line version of Wireshark called TShark with the same functionality. Wireshark essentially "understands" the formats of various types of network packets, and is able to display the header and content information of captured packets in an easy-to-read format with various filtering options. Packets can be either captured directly with Wireshark, or captured with a separate utility and later viewed within Wireshark. As a powerful (and free) network analysis tool, Wireshark has become an industry standard utility for network traffic analysis.

Zeus

Zeus is a well-known Trojan Horse that steals financial information from a user's browser using man-in-the-browser key logging and form grabbing. Additionally, Zeus installs a backdoor on the machines it infects, so these machines can become part of a botnet used for distributed denial-of-service (DDoS) attacks and other malicious activities. Zeus was first detected in 2007 when it was used to attack the United States Department of Transportation, however, it did not become significantly widespread until March 2009. Attacks involving the use of Zeus occurred throughout 2010, including an October 2010 attack by a large organized

crime ring attempting to steal over $70M from individuals in the US with Zeus-infected computers. The FBI made over 90 arrests of suspected members in the US, and various others were arrested in the UK and Ukraine in connection with the attack. In May 2011 the source code of the version used then of Zeus (v2) was leaked, leading to various customized Zeus-based bots being created. Some of the more advanced custom bots based on the leaked code (such as Ice IX) attempted to fix many of the existing issues with Zeus rendering it even harder to detect. However, many security researchers have discovered that even the most well-known custom versions are extremely similar to the original leaked Zeus source code, and are therefore not significantly more innovative or dangerous.

Zero-Day/Zero-Minute Attack

A Zero-Day (or Zero-Minute) Attack is a type of attack that uses a previously unknown vulnerability. Because the attack is occurring before "Day 1" of the vulnerability being publicly known, it is said that the attack occurred on "Day 0" - hence the name. Zero-Day exploits are highly sought after - often bought and sold by private firms anywhere from $5,000 to $250,000, depending on what applications and operating systems they target - as they almost guarantee that an attacker is able to stealthily circumvent the security measures of his or her target. Private security firms aside, software vendors will also usually offer a monetary reward among other incentives to report zero-day vulnerabilities in their own software directly to them.

Zombie

A "zombie" or "bot" is a compromised computer under the control of an attacker who often controls many other compromised machines that together make up a botnet. The term "zombie" was coined to describe such an infected computer because the computer's owner is often not aware that his or her computer is being used for malicious activities.
